This report concerns a study which was conducted for SKB. The conclusions and viewpoints presented in the report are those of the author(s) and do not necessarily coincide with those of the client.

Abstract

The Prototype Repository Test consists of two sections. The installation of the first Section of Prototype Repository was made during summer and autumn 2001 and Section 2 was installed in spring and summer 2003.

This report presents data from measurements in the Prototype Repository during the period 010917-051201. The report is organized so that the actual measured results are shown in Appendix 1-10, where Appendix 8 deals with measurements of canister displacements (by AITEMIN), Appendix 9 deals with geo-electric measurements in the backfill (by GRS), Appendix 10 deals with stress and strain measurement in the rock (by BBK) and Appendix 11 deals with measurement of water pressure in the rock (by VBB/VIAK). The main report and Appendix 1-7 deal with the rest of the measurements.

Section 1

The following measurements are made in the bentonite in each of the two instrumented deposition holes in Section 1 (1 and 3): Temperature is measured in 32 points, total pressure in 27 points, pore water pressure in 14 points and relative humidity in 37 points. Temperature is also measured by all relative humidity gauges. Every measuring point is related to a local coordinate system in the deposition hole.

The following measurements are made in the backfill in Section 1. Temperature is measured in 20 points, total pressure in 18 points, pore water pressure in 23 points and relative humidity in 45 points. Temperature is also measured by all relative humidity gauges. Furthermore, water content is measured by an electric chain in one section. Every measuring point is related to a local coordinate system in the tunnel.

The following measurements are made on the surface of the canisters in Section 1: Temperature is measured every meter along two fiber optic cables. Furthermore, displacements of the canister in hole 3 are measured with 6 gauges.

The following measurements are made in the rock in Section 1: Temperature is measured in 37 points in boreholes in the floor. Water pressure is measured in altogether 64 points in 17 boreholes all around the tunnel.

Section 2

The following measurements are made in the bentonite in each of the two instrumented deposition holes in Section 2 (5 and 6): Temperature is measured in 29 points, total pressure in 27 points, pore water pressure in 14 points and relative humidity in 47 points deposition hole 5 and in 65 points in deposition hole 6. Temperature is also measured by all relative humidity gauges.

The following measurements are made in the backfill in Section 2. Temperature is measured in 16 points, total pressure in 16 points, pore water pressure in 18 points and relative humidity in 32 points. Temperature is also measured by all relative humidity gauges. Furthermore, water content is measured by an electric chain in one section. Every measuring point is related to a local coordinate system in the tunnel.

The following measurements are made on the surface of the canisters in Section 2: Temperature is measured every meter along two fiber optic cables. Additional to this temperature measurement three conventional thermocouples are placed on each canister. Furthermore, displacements of the canister in hole 6 are measured with 6 gauges.

The following measurements are made in the rock in Section 2: Temperature is measured in 24 points in boreholes close to the deposition holes. Relative humidity is also measured in 6 points in the rock close to deposition hole 6.

Conclusions

A general conclusion is that the measuring systems and transducers work well, but the number of sensors that has failed is increasing. 196 out of 363 sensors in Section 1 (excluding water pressure sensors in the rock, geo-electric measurements) are out of order, the majority being RH-sensors that fail at water saturation. 84 out of 394 sensors in Section 2 (excluding water pressure sensors in the rock, geo-electric measurements, stress and strain in the rock and displacement of canister) are out of order, some of them due to problems with the data collection system. Furthermore some suction sensors (20) placed in the backfill is not giving reliable values due to high degree of saturation (RH 100%). A new calibration of the fiber optic cables for temperature measurement on the surface of the canisters has been made but it is still preliminary, which means that adjustments of the results may be done afterwards.

The drainages of the inner section together with the drainage of the outer plug were closed at the beginning of November. The pressure (pore pressure and total pressure) both in the backfill and in some parts of the buffer in the six deposition holes increased after this date. At the beginning of December 2004 damages was observed on two of the canisters (canister No 2 and No 6). The power to all of the canisters was then switched off and the drainage of the tunnel was opened. The power of canisters was switched on again on December 15 except for canister No 2 which was out of order. The drainage of the tunnel was kept open. The increase in pore pressure affected the saturation rate of the backfill and the buffer. The failure of canister No 2 and the time when the power was switched off affected also the measurements especially the temperature measurements in the buffer. At the beginning of September 2005 more problems with the power to canister 6 was observed. The power to the canister was switched off for about 2 months. The power to canister 6 was switched on again on November 2 2005.

Sammanfattning

Prototypförvaret består av två sektioner. Den första sektionen installerades under sommaren och hösten 2001 och Sektion 2 installerades under våren och sommaren 2003.

I denna rapport presenteras data från mätningar i Prototypförvaret för perioden 010917-051201. Rapporten är uppdelad så att själva mätresultaten redovisas i Appendix 1-10, varvid Appendix 8 behandlar mätning av kapselförskjutningar (görs av AITEMIN), Appendix 9 behandlar geoelektriska mätningar i återfyllningen (görs av GRS), Appendix 10 behandlar mätningar av spänning och töjning i berget (handhas av BBK) och Appendix 11 behandlar vattentrycksmätningar i berget (handhas av VBB/VIAK). I själva huvudrapporten och Appendix 1-7 behandlas alla övriga mätningar.

Sektion 1

Följande mätningar görs i bentoniten i vardera av de två instrumenterade deponeringshålen i Sektion 1 (1 och 3): Temperatur mäts i 32 punkter, totaltryck i 27 punkter, porvattentryck i 14 punkter och relativa fuktigheten i 37 punkter. Temperaturen mäts även med relativa fuktighetsmätare. Varje mätpunkt relateras till ett lokalt koordinatsystem i deponeringshålet.

Följande mätningar görs i återfyllningen i Sektion 1: Temperaturen mäts i 20 punkter, totaltryck i 18 punkter, porvattentryck i 23 punkter och relativa fuktigheten i 45 punkter. Temperaturen mäts även med alla relativa fuktighetsmätare. Varje mätpunkt relateras till ett lokalt koordinatsystem i tunneln. Dessutom mäts vatteninnehållet i en sektion med en geoelektrisk mätkedja.

Följande mätningar görs på ytan i kapselns kopparhölje i samtliga 4 kapslar i Sektion 1: Temperatur mäts varje meter längs två fiberoptiska kablar från två håll. Dessutom mäts förskjutningar av kapseln i hål 3 med 6 givare.

Följande mätningar görs i berget i Sektion 1: Temperatur mäts i borrrål i 37 punkter i golvet. Vattentryck mäts i sammanlagt 64 punkter i 17 borrrål runt hela tunneln.

Sektion 2

Följande mätningar görs i bentoniten i vardera av de två instrumenterade deponeringshålen i Sektion 2 (5 och 6): Temperatur mäts i 29 punkter, totaltryck i 27 punkter, porvattentryck i 14 punkter och relativa fuktigheten i 47 punkter i deponeringshål 5 och 65 punkter i deponeringshål 6. Temperaturen mäts även i alla relativa fuktighetsmätare.

Följande mätningar görs i återfyllningen i Sektion 2: Temperaturen mäts i 16 punkter, totaltryck i 16 punkter, porvattentryck i 18 punkter och relativa fuktigheten i 32 punkter. Temperaturen mäts även med alla relativa fuktighetsmätare. Varje mätpunkt relateras till ett lokalt koordinatsystem i tunneln. Dessutom mäts vatteninnehållet i en sektion med en geoelektrisk mätkedja.

Följande mätningar görs på ytan i kapselns kopparhölje i de två kapslarna i Sektion 2: Temperaturen mäts varje meter längs två fiberoptiska kablar från två håll. Vidare mäts temperaturen i tre punkter på varje kapsel med konventionella termoelement. Även förskjutningen av kapseln i deponeringshål 6 mäts med 6 givare.

Temperatur mäts i berget kring varje kapsel i 24 punkter. Vidare mäts RH i berget kring deponeringshål 6 i 6 punkter.

Slutsatser

En generell slutsats är att mätsystemen och givarna tycks fungera bra. 196 av 363 givare i Sektion 1 (med undantag av vattentrycksmätare i berget) fungerar inte. Många av dessa (64 stycken) är RH-mätare som slutar fungera vid vattenmättnad. 84 av 394 givare i Sektion 2 (med undantag av vattentrycksmätare i berget) fungerar inte, en del av dessa p.g.a. datascan problem. Dessutom har en del psychrometrar (21) placerade i återfyllningen slutat att ge relevanta värden på grund av att fyllningen närmar sig vattenmättnad. Kalibrering av de fiberoptiska kablarna för temperaturmätning på kapselytorna har gjorts men den är fortfarande preliminär varför nya efterjustering av resultaten kan bli aktuell.

Dräneringen av den inre sektionen och den ytterre pluggen stängdes i början av november. Portrycket och totaltrycket både i återfyllnaden och i bufferten ökade markant efter stängningen av dränaget. Ökningen av portrycket påverkade också vattenmättnaden i vissa delar av buffert och återfyllnade. Skador observerades på två av kapslarna i början av december 2004, varefter effekten till samtliga kapslar stängdes av samtidigt som dräneringen av tunneln öppnades. Effekten till alla kapslar utom kapsel nr. 2 sattes på igen den 15:e december. Skadorna på kapsel 2 var så omfattande att det inte var möjligt att koppla in någon effekt på denna. Dräneringen av tunneln förblev öppen. I början av september 2005 uppstod nya problem med kapsel Nr 6. Effekten till kapseln stängdes av under ca 2 månader. Från och med den 2:a november 2005 sattes effekten till kapsel Nr 6 på igen.

1 Introduction

The Prototype Repository Test consists of two sections. The installation of the first Section of Prototype Repository was made during summer and autumn 2001 and Section 2 was installed in spring and summer 2003.

Section 1 consists of four full-scale deposition holes, copper canisters equipped with electrical heaters, bentonite blocks and a deposition tunnel backfilled with a mixture of bentonite and crushed rock and ends with a concrete plug as shown in Figure 1-1. Section 2 consists of two full-scale deposition holes with a backfilled tunnel section and ends also with a concrete plug.

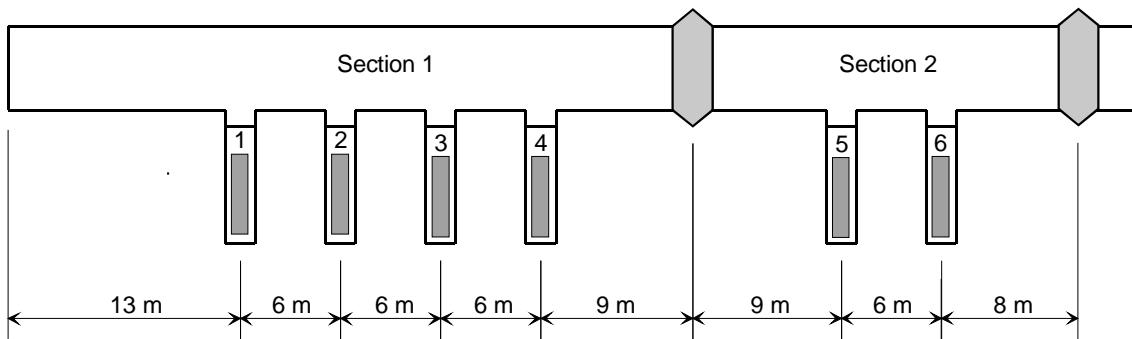

Figure 1-1. Schematic view of the Prototype Repository.

The bentonite buffer in deposition holes 1, 3, 5 and 6, the backfill and the surrounding rock are instrumented with gauges for measuring temperature, water pressure, total pressure, relative humidity, resistivity and canister displacement. The instruments are connected to data collection systems by cables protected by tubes, which are led through the rock in watertight lead throughs.

In general the data for Section 1 in this report are presented in diagrams covering the time period 2001-09-17 to 2004-12-01. The time axis in the diagrams represent number of days from start 2001-09-17, which is the day the heating of the canister in hole 1 was started. For Section 2 the date are presented in diagrams covering the time period 2003-05-08 to 2004-12-01, where 2003-05-08 is the day when the heating of the canister in hole 5 was started.

This report consists of several parts. In chapters 2, 3, 4 and 6 a test overview with the positions of those measuring points and a brief description of the instruments are shown. In chapter 5 the measured results from all measurements in Section 1, except canister displacement, stress and strain and water pressure in the rock and resistivity in the backfill and buffer, are presented and commented. Corresponding presentations and comments for Section 2 are made in chapter 7. The diagrams of those measured results are attached in Appendix 1-7. The results and comments of the measurements of canister displacement, resistivity in the backfill, stress and strain in the rock and water pressure in the rock are presented separately in Appendix 8-11.

A quick guide to the positions of the instruments in the buffer and backfill is enclosed as the last page.

2 Geometry and coordinate systems

The Prototype Repository consists of two sections as shown in Figure 1-1. The geometry and the coordinate system for the sensors are different for the deposition holes and the tunnel. The temperature sensors in the rock are defined with the same coordinate system as the deposition holes.

Deposition holes

In Section 1 the deposition holes are termed 1-4 according to Figure 1-1 and in Section 2 the deposition holes are termed 5 and 6. The coordinate system for these holes is shown in Figure 2-1. With the z -axis starting from the cement casting and the angle α counted anti-clockwise from direction A. Measurements are mainly made in four vertical sections A, B, C and D according to Figure 2-1. Direction A and C are placed in the tunnels axial direction with A headed against the end of the tunnel i.e. almost towards West.

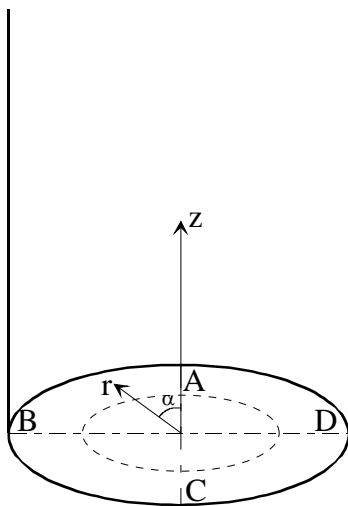

Figure 2-1. Figure describing the instrument planes (A-D) and the coordinate system used when describing the instrument positions.

Tunnel

The coordinate system of the backfill in the tunnel is shown in Figure 3-2. The coordinate y starts at the entrance on ground, which means that the tunnel ends at $y = 3599, 8$. The y-axis runs in the center of the tunnel, which means that the tunnel walls intersect the z and x-axes at ± 2.5 m. The z-coordinate is determined positive upwards and the x-coordinate is determined positive to the right when facing the end of the tunnel.

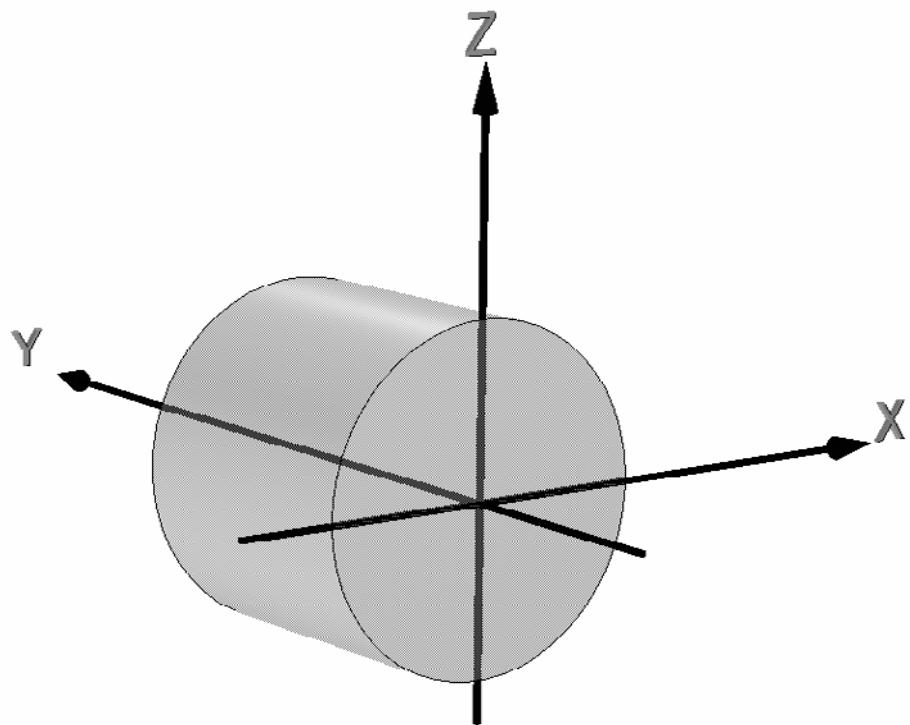

Figure 2-2. Coordinate system of the tunnel.

3 Brief description of the instruments

The different standard instruments that are used in the buffer, backfill and rock (temperature) are briefly described in this chapter.

Measurements of temperature

Buffer, backfill and rock

Thermocouples from Pentronic have been used to measure temperature. Measurements are done in 32 points in each instrumented hole (hole 1 and hole 3). In addition, temperature gauges are built into the capacitive relative humidity sensors and some of the other sensor types as well.

Canister

Temperature is measured on the surface of the canister with optical fiber cables. An optical measuring system called FTR (Fiber Temperature Laser Radar) is used. In Section 2 are also three thermocouples of type Pentonic installed on each canister.

Measurement of total pressure in the buffer and backfill

Total pressure is the sum of the swelling pressure and the pore water pressure. It is measured with the following instrument types:

- Geocon total pressure cells with vibrating wire transducers.
- Kulite total pressure cells with piezo resistive transducers.

Measurement of pore water pressure in the buffer and backfill

Pore water pressure is measured with the following instrument types:

- Geocon pore pressure cells with vibrating wire transducer.
- Kulite pore pressure cells with piezo resistive transducer.

Measurement of the water saturation process in the buffer and backfill

The water saturation process is recorded by measuring the relative humidity in the pore system, which can be converted to total suction (negative water pressure). The following techniques and devices are used:

- Vaisala relative humidity sensor of capacitive type. The measuring range is 0-100 % RH.
- Rotronic relative humidity sensors of capacitive type. The measuring range is 0-100 % RH.
- Wescor soil psychrometer. The sensor is measuring the dry and the wet temperature in the pore volume of the material. The measuring range is 95.5-99.6 % RH corresponding to the pore water pressure -0.5 to -6 MPa. Psychrometers are placed in the backfill in both sections and in the buffer in the two deposition holes in Section 2.

4 Location of instruments in Section 1

4.1 Strategy for describing the position of each device in the bentonite and rock in and around the deposition holes

The same principles are used for describing the position of all sensors in the bentonite inside the deposition holes as well as the thermocouples in the rock around the deposition holes. The principles are described in the quick guide inserted as a folded A3 page at the end of the report.

Every instrument is named with a unique name consisting of 1 letter describing the type of measurement, 2 letters describing where the measurement takes place (buffer, backfill, rock or canister), 1 figure denoting the deposition hole (1-4) and 4 figures specifying the instrument according to a separate list (see Table 2-1 to 2-10). Every instrument position is then described with three coordinates according to Figure 3-1.

The r -coordinate is the horizontal distance from the center of the hole and the z -coordinate is the height from the surface of the bottom casting of the hole (the block height is set to 500mm). The α -coordinate is the angle from the vertical direction A (almost West).

Figure 4-1 shows an overview of the instruments in the buffer. The bentonite blocks are called cylinders and rings. The cylinders are numbered C1-C4 and the rings R1-R10 respectively.

- pore water pressure + temp.
- total pressure + temp.
- ✗ temp.
- △ relative humidity (+ temp.)

1m

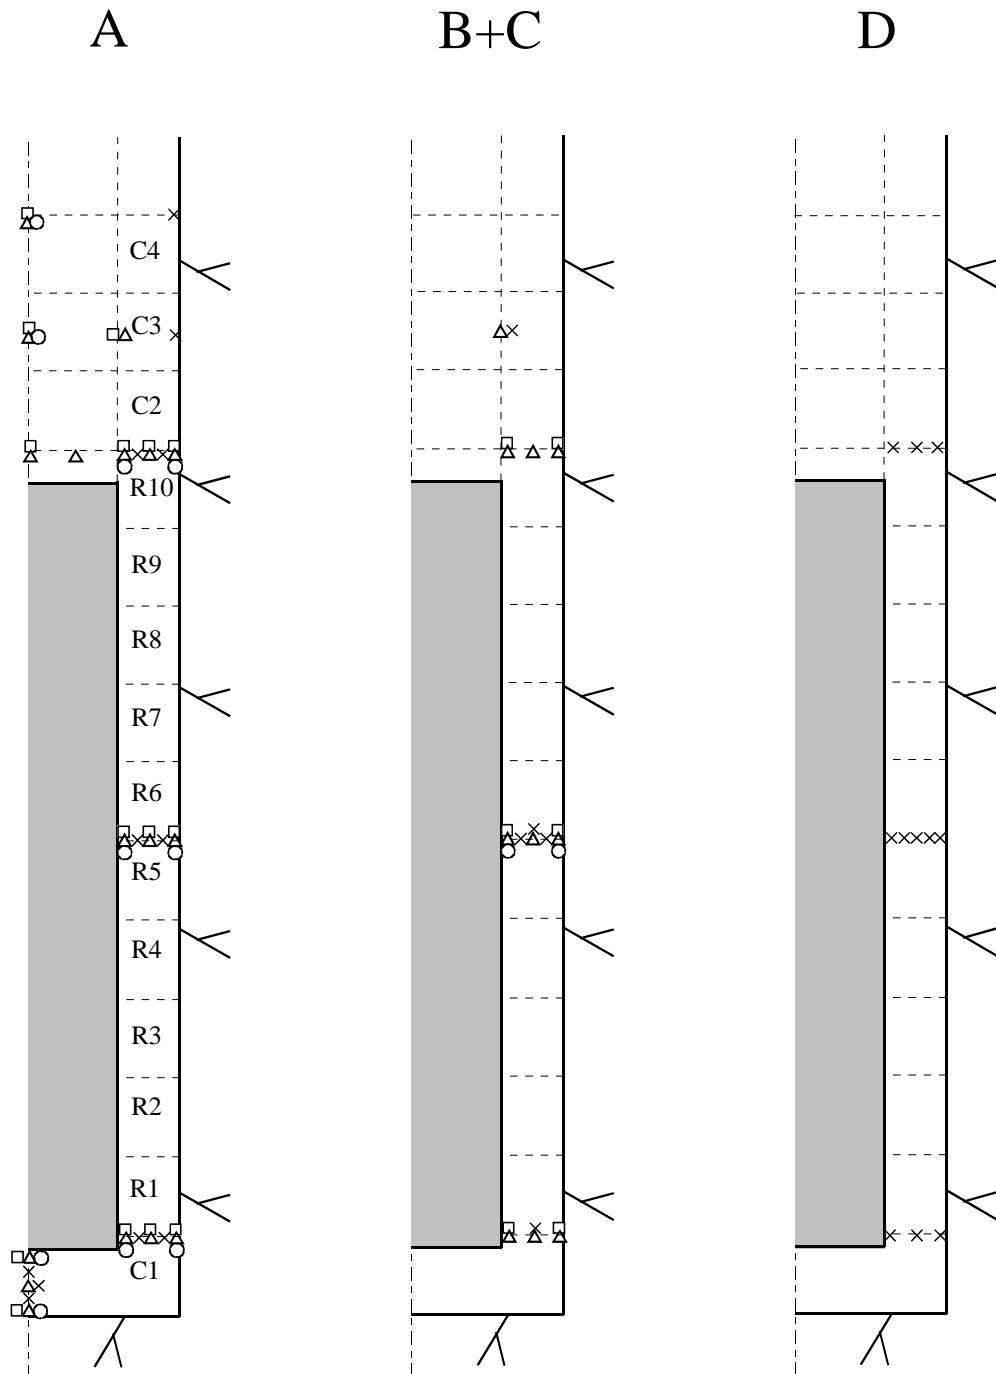

Figure 4-1. Schematic view over the instruments in four vertical sections and the block designation.

4.2 Position of each instrument in the bentonite in hole 1 (DA3587G01)

The instruments are located in three main levels in the blocks, 50 mm, 160 mm and 250 mm, from the upper surface. The thermocouples are mostly placed in the 50 mm level and the other gauges in the 160 mm level except for the Geokon type 1 pressure sensors and the Rotronic humidity sensors, which are placed in the 250 mm level depending on the size of the sensor house.

Exact positions of the sensors are described in Tables 4-1 to 4-4.

Table 4-1 Numbering and position of instruments for measuring temperature (T) in the buffer in hole 1.

Type and number	Block	Instrument position				Fabricate	Remark
		Direction	α	r	Z		
		degree	m	m

4.4 Instruments on the canister surface in holes 1-4

The canisters are instrumented with optical fiber cables on the copper surface.

Figure 4-2 shows how two optical fiber cables are placed on the canister surface. Both ends of a cable are used for measurements. This means that the two cables are used for four measurements.

With this laying the cables will enter and exit the surface at almost the same position. Curvatures are shaped as a quarter circle with a radius of 20 cm. The cables are placed in a milled out channels on the surface. The channels have a width and a depth of just above 2 mm

In additional to the optical cables one thermocouple (TBU 10006) is fixed to the lid of the canister in deposition hole 2 (see Table 4-1).

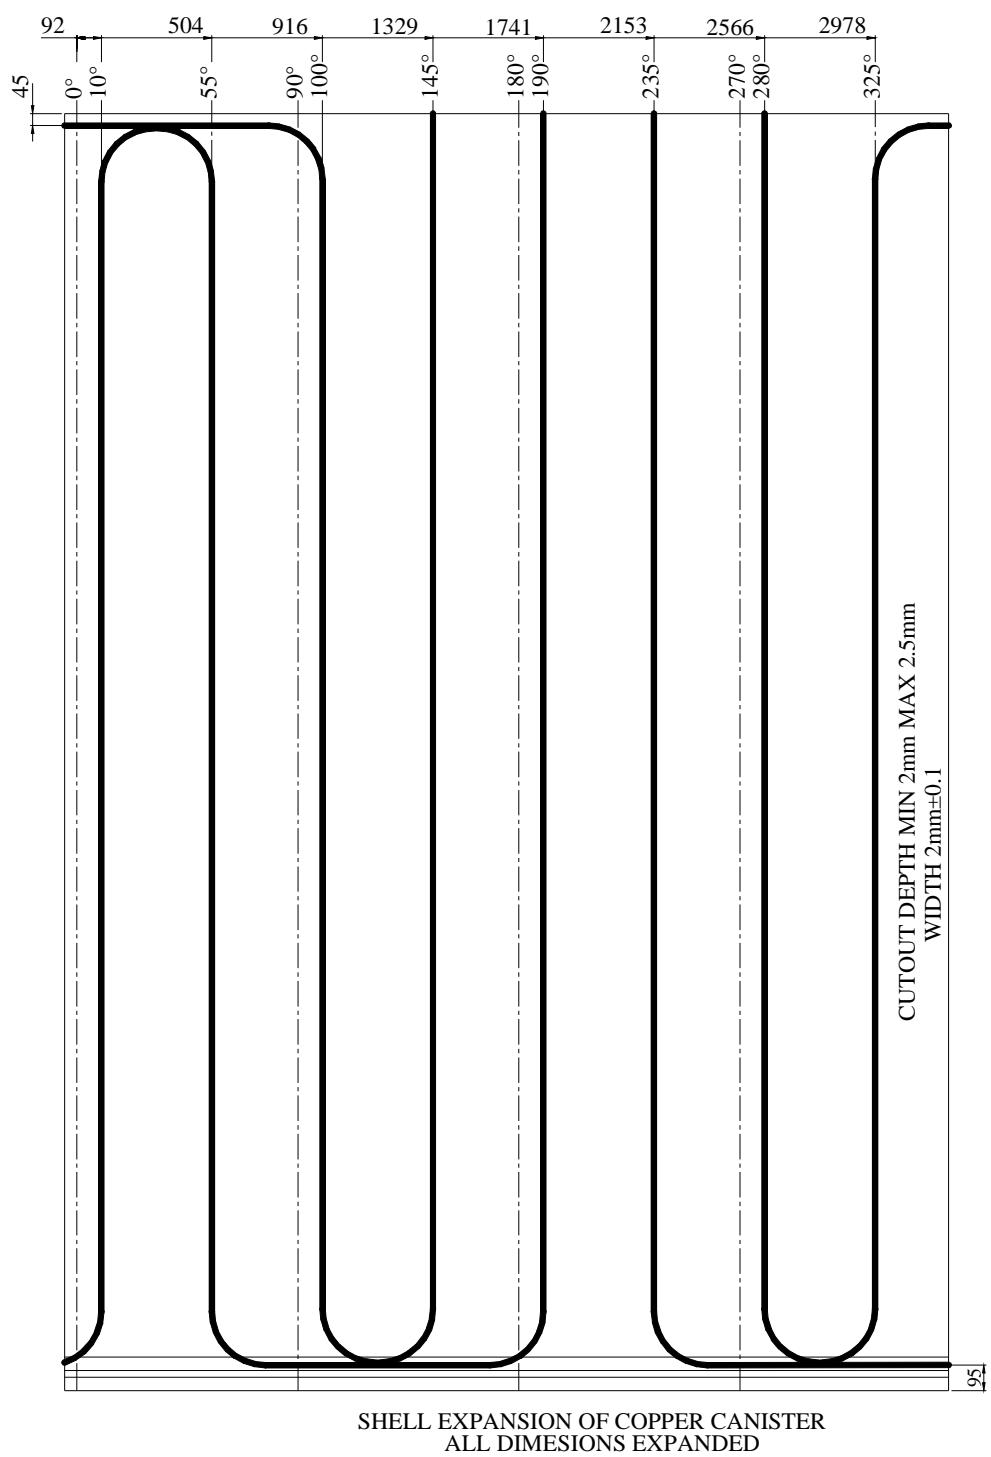

Figure 4-2. Laying of the optical fiber cables with protection tube of Inconel 625 (outer diameter 2 mm) for measurement of the canister surface temperature (surface unfolded)

4.5 Position of temperature sensors in the rock

The positions of the temperature sensors in the rock are termed in the same way as the sensors in the buffer in the deposition holes. Figure 4-3 shows an overview of the temperature sensors placed in the rock. The sensors are assigned to the closest deposition hole. The positions are described in Table 4-10.

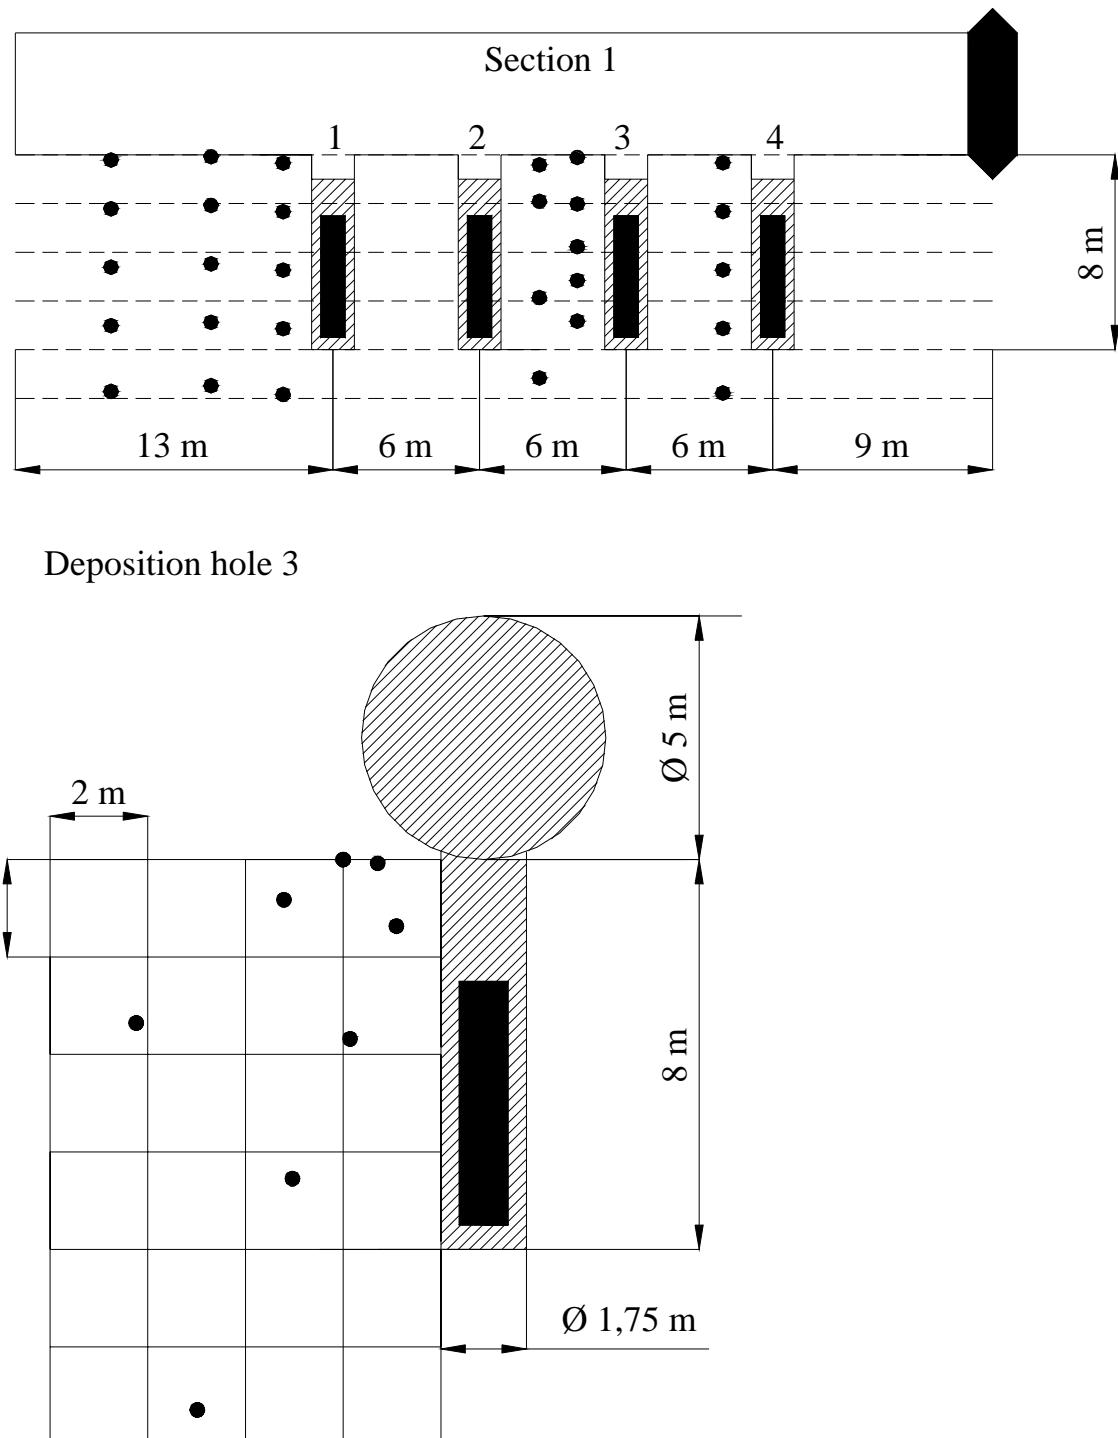

Figure 4-3. Overview of the temperature sensors in the rock. Length section (upper) and cross section (towards the end of the tunnel)

4.6 Strategy for describing the position of each device in the backfill in section 1

The principles of terming the instruments are described in the quick guide inserted as a folded A3 page at the end of the report.

Every instrument is named with a unique name consisting of 1 letter describing the type of measurement, 2 letters describing where the measurement takes place (buffer, backfill, rock or canister) and 5 figures specifying the instrument according to separate lists (see Tables 4-11 to 4-14). Every instrument position is then described with three coordinates according to Figure 2-2. The x -coordinate is the horizontal distance from the center of the tunnel and the z -coordinate is the vertical distance from the center of the tunnel. The y -coordinate is the same as in the tunnel coordinate system, i.e. $y=3599$ corresponds to the end of the tunnel.

The backfill is mainly instrumented in vertical sections straight above and between the deposition holes (Figures 4-4 and 4-5).

- pore water pressure + temp.
- total pressure + temp.
- ×
- △ relative humidity (+ temp.)
- E, F measuring sections

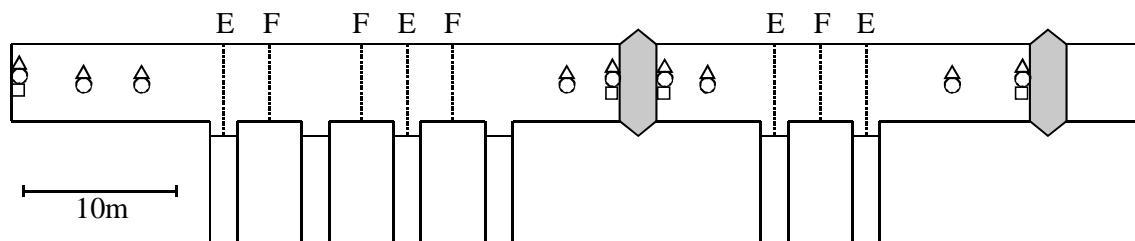

Figure 4-4. Schematic view over the instrumentation of the backfill

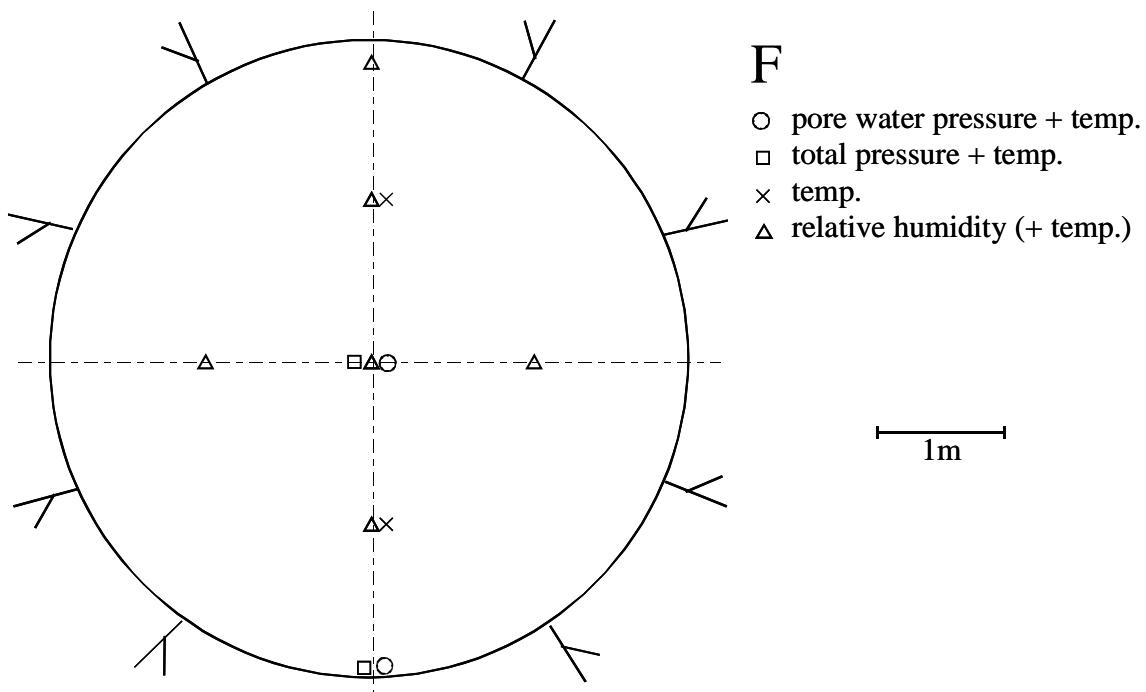

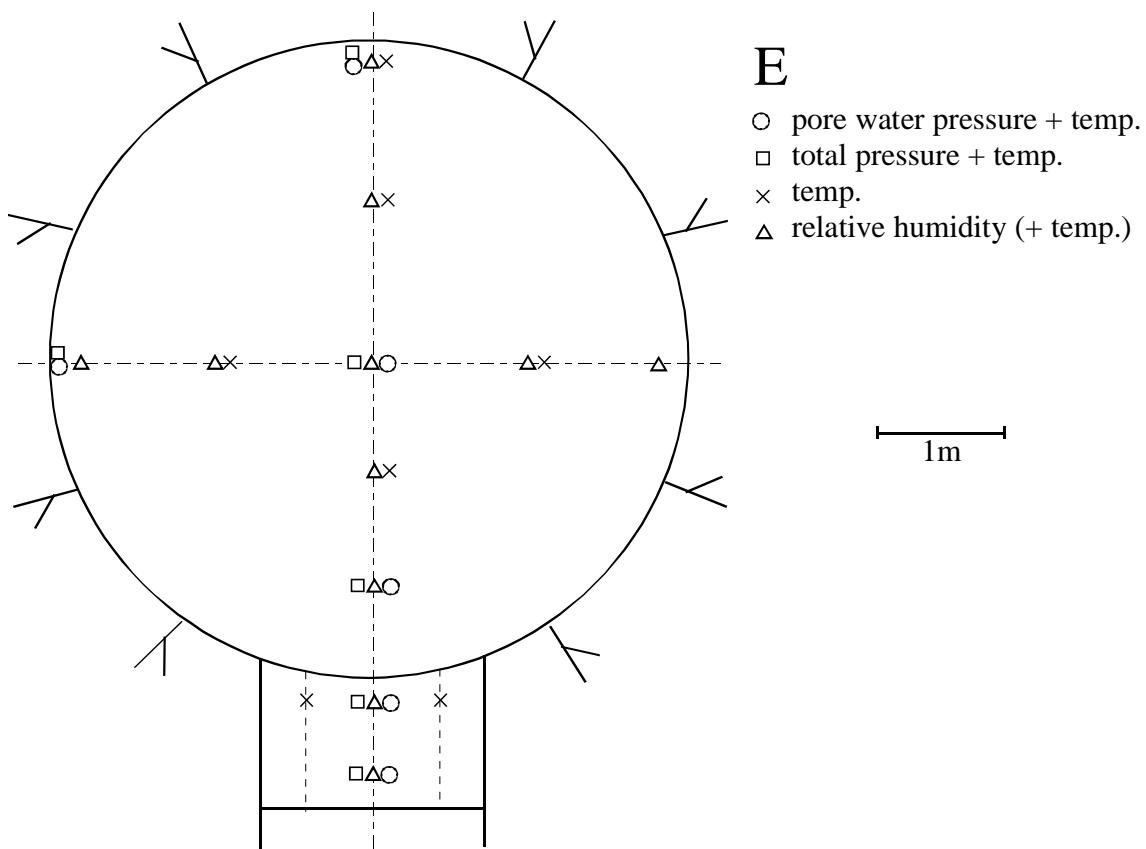

Figure 4-5. Schematic view over the sensors positions in the different sections.

4.7 Position of each instrument in the backfill

The positions of each instrument are described in Tables 4-11 to 4-14.

5 Results and comments for Section 1

5.1 General

In this chapter short comments on general trends in the measurements are given. Sensors that are not delivering reliable data or no data at all are noted and comments on the data collection in general are given.

The heating of the canister in hole 1 started with an applied constant power of 1800 W at 010917. This date is also marked as start date. The backfilling started 010903 and was finished 011120 and the plug was cast at 011214. In order to simulate the radioactive decay, the power was decreased 20 W one year after start of the first heater. At the beginning of September 2004 the power was decreased with about 30 W to 1710 W in deposition holes 1-4. Table 5-1 shows some important dates for section 1. At the beginning of November the drainage of the inner part of Section 1 and the drainage through the outer plug were closed. At the beginning of December damages were observed on one canister in Section 1 (No 1) and one in Section 2 (No 6) probably due to high water pressure in the buffer and backfill. It was then decided to switch off the power to all canisters. This was done on December 2. The drainage of the tunnel was opened on December 6 and investigations on the damaged canisters were initialized. The power to all the canisters, except for canister 2, was on December 15 switched on. The damages on canister 2 were so severe that it was impossible to apply any power in this canister. The drainage of the tunnel was kept open.

Table 5-1. Key dates for section 1

Activity	Date	
Start backfilling	3/9	2001
Start heating canister 1	17/9	2001
Start heating canister 2	24/9	2001
Start heating canister 3	11/10	2001
Start heating canister 4	22/10	2001
Finish backfilling	20/11	2001
Plug casting	14/12	2001
Decreased power (-20 W)	17/9	2002
Decreased power (-40 W)	5/9	2003
Decreased power (-30 W)	8/9	2004
The drainage of tunnel was closed	1/10	2004
The power to all canisters was switched off	2/12	2004
The drainage of the tunnel was opened	6/12	2004
The power to the canisters was switched on	15/12	2004

Beside the above reported power reductions a change in power was made June 23 2003 due to additional calculations of the power from measurement of the energy. The power of the canisters was adjusted to 1800 W. The most significant change was made for canister 2 (See section 5.4.1 and Appendix 3 page 138).

About 196 out of 363 sensors (excluding water pressure sensors in the rock and the displacement sensors for the canister) are out of order, the majority being RH-sensors that fail at water saturation and thermocouples in deposition hole 3.

The measured processes were slow up to about 20 days after the drainage of the tunnel was closed. Very small changes of the measured parameters occurred up to that date. After that the readings from some of the total and pore pressure sensors placed in the buffer reacted strongly (quick increase in pressure). Also the total and pore pressure sensors placed in the backfill recorded high pressures caused by the closing of the drainage. After the reopening of the drainage of the tunnel, both the pore pressures and the total pressures were stabilized on almost the same level as before the closing of the drainage.

So far hole 1 has been strongly wetted but very little wetting is observed in hole 3. A slow but obvious wetting of the backfill is noted until about 20 days after the closing of the drainage. After that a strong increase of the wetting rate was monitored by several psychrometers. The measurement of the temperature on the canister surface with the optical system has stopped functioning.

5.2 Deposition hole 1

5.2.1 Total pressure

Geokon (App. 1\pages 85-87)

The measured pressure range is from 0 to 8.5 MPa. The highest pressure is indicated from the peripheral sensors in the bottom block (C1). Four sensors in block R5 and block R10 yielded a high increase in total pressure when the drainage of the tunnel was closed. Most of the sensors yielded a drop in pressure when the heaters where switched off and the drainage of the tunnel was opened again and an increase in pressure when the heaters where switched on again.

Eleven sensors are out of order.

Kulite (App. 1\page 88)

The highest pressure 7 MPa is indicated from the peripheral sensor (PBU 10012) in block R5. Three of the installed sensors indicated a rapid increase in pressure when the drainage of the tunnel was closed followed by a drop in pressure when the power was switched off and the drainage was reopened. After the power was switched on the pressure increased to the same level as before the closing of the drainage.

Two sensors were not installed and five of the installed sensors are out of order.

5.2.2 Relative humidity

Vaisala (App. 1\pages 89-92)

Since temperature is also measured with all relative humidity sensors, the diagrams include those measured temperatures. The temperature measurements start at about 16 degrees while the RH measurements start at about 70 %RH.

The relative humidity has not changed very much during the last 6 months, except for the sensors placed above the canister (in Cylinder 3 and 4) which are indicating a slowly wetting. The temperature measurements were effected when the power to the heaters was switched off but reached similar levels as before when the power was switched on again.

Fourteen sensors are out of order, most of them due to water saturation.

Rotronic (App. 1\pages 93-97)

All Rotronic sensors placed between the canister and the rock show RH higher than 90%.

Two of the sensors placed in the central part of block C1 are indicating a drying of the bentonite (decreasing in RH from about 75%)

Sixteen sensors are out of order, most of them due to water saturation.

5.2.3 Pore water pressure

Geokon (App. 1\page 98)

The highest pressures 500-1450 kPa are measured near the canister surface in block R5 (UBU10005) and in the periphery of block R5 (UBU10010). One sensor in block C1 is also recording an increasing pressure (UBU1003) while the rest of the sensors are measuring very low pressures.

Two sensors are out of order.

Kulite (App. 1\page 99)

A rather high water pressure is noted from three sensors located in block R5 (1200 – 3500 kPa). The pore pressure measured with two of the sensors reacted strongly during the period when the drainage of the tunnel was closed and during the period when the power to the canister was switched off.

Two sensors are out of order.

5.2.4 Temperature in the buffer (App. 1\pages 100-106)

The latest measured temperature ranges from 29.0 °C (in the periphery of the upper bentonite cylinder C4) to 69.0 °C in the center close to the canister. The highest temperature gradient is 0.60 °C /cm (block R5).

Twenty sensors are out of order.

The temperature in the buffer is also measured with the Geokon sensors (from day 1350). The maximum temperature recorded with these sensors is about 63 °C at the end of this measuring period (PBU10002 placed in the center of block C1 close to the canister).

5.2.5 Canister power in dep. hole 1 (App. 1\page 110)

The power of the canister in hole 1 has been kept constant during one year at 1800 W since the start 010917. After one year the power was decreased with about 20 W. After another year the power was decreased with about 40 W. The latest reduction of power was made at the beginning of September year 2004 (about 30 W). After this reduction the power of the canister in hole 1 was about 1710 W. During the period between December 6 and December 15 the power to the canister was switched off. After that period the power was adjusted to about 1710 W again.

5.2.6 Temperature on the canister surface (App. 1\pages 111-112)

The first diagram shows the maximum temperature, measured with the optical cables placed on the surface of the canister, plotted as function of time. The maximum measured temperature on the canister surface is about 75 °C. With no damages on the optical cables this plot should have four curves. Only one curve with relevant values is presented here up to December 24 which indicates that the optical cables are damaged. The second diagram shows the distribution of the temperature along the optical cables at December 1 2004. The length of the cables on the canister surface is about 20 m. The variation of a few degrees is caused by the difference in temperature in the center and ends of the canister. At December 15 the optical system for measuring the temperature on this canister stopped functioning.

5.3 Deposition hole 3

5.3.1 Total pressure

Geokon (App. 2\pages 115-117)

Most of the sensors placed in block C1 and block R10 yielded an increase in total pressure when the drainage of the tunnel was closed.

The total pressure measured in this deposition hole is significantly lower than those measured I deposition hole 1. The maximum pressure registered at the end of this measuring period is 3.2 MPa. Four out of 16 sensors show a pressure higher than 500 kPa.

Kulite (App. 2\pages 118-119)

The highest pressure, 1.8 MPa, is indicated from the peripheral placed sensors in block R10. The sudden change in pressure that occurred after about 180 days was probably caused by early data logger problems.

Seven sensors are out of order since earlier and three sensors are showing negative pressures.

5.3.2 Relative humidity

Vaisala (App. 2\pages 120-123)

A significant drying of the bentonite close to the top of the canister was observed by the two sensors WBU30022 and WBU30023. After the closing of the drainage both sensors indicated a significant increasing in relative humidity. An increased wetting of the bentonite can be observed by sensors placed in block R10 between the canister and the rock. One sensor placed in block R5 showed an increase in relative humidity from about 70% to 82% after the closing of the drainage. The changes in the relative humidity in the buffer measured by the rest of the sensors are very small.

Ten sensors are out of order.

Rotronic (App. 2\pages 124-128)

Many Rotronic sensors in hole 3 have failed or increased the measured RH to 100%. The reason for this is unclear. Since there are no other signs of strong wetting, malfunction are more probable than strong wetting. One sensor (WBU30016) placed close to the canister in block R5 was indicating a drying of the bentonite until it failed.

Sixteen sensors are at present out of order.

5.3.3 Pore water pressure.

Geokon (App. 2\page 129)

All sensors yield very low pressure except for one sensor below the heater that yields a sudden increase to 220 kPa (questionable).

Kulite (App. 2\page 130)

UBU30004 yields a pressure of 440 kPa and this sensor is placed near the rock surface at the bottom of the deposition hole. The other sensors yield very low pressures.

5.3.4 Temperature in the buffer (App. 2\pages 131-137 and 140)

The measured temperature ranges from 38 °C (in the periphery of the upper bentonite cylinder C4) to a temperature of 83.2 °C in the center close to the canister. These measurements were made just before the power to the canisters were switched off. The highest temperature gradient is 0.59 °C/cm (block R5). There have appeared some problems with some data scan units, which explains the noise in some curves.

28 sensors are out of order.

The temperature in the buffer is also measured with the Geokon sensors (from day 1350). The maximum temperature recorded with these sensors is about 82 °C at the end of this measuring period (PBU30002 placed in the center of block C1 close to the canister).

5.3.5 Canister power (App. 2\page 141)

The power of the canister in hole 3 has been kept constant at 1800 W from the start 011011 until 020917, when the power was decreased with about 20 W. Some initial problems have been overcome. The power has been stepwise decreased according to Table 5-1. During the period between December 6 and December 15 the power of all canisters was switched off. After that period the power was adjusted to about 1710 W.

5.3.6 Temperature on the canister surface (App. 2\pages 142-143)

The first diagram shows the maximum temperature plotted as a function of time. The maximum measured temperature on the canister surface was about 100 °C just before the power to the canisters was switched off. The temperature recovered, but only to about 93 °C after the power was switched on again and after that a slight decrease in temperature was measured until the sensor stopped functioning at the end of August 2005. The second diagram shows the distribution of the temperature along the cables. See also chapter 5.2.6.

5.4 Deposition hole 2

5.4.1 Canister power (App. 3\page 148)

The power of the canister in hole 2 has been kept constant at 1800 W from the start 010924 until 020917, when the power was decreased with about 20 W. After two years (September 2003) the power was decreased with about 40 W to 1740 W. The interruption in the curve between days 409 and 456 is caused by data collection problems. At the beginning of September 2004 the power was decreased with about 40 W to 1710 W. Since permanent damages on the heaters in the canister were observed on December 1 the power to this canister has been switched off and not been restarted.

5.4.2 Temperature on the canister surface (App. 3\pages 149-151)

See chapter 5.2.6. The maximum measured temperature on the canister surface is at present 91 °C. The reason for the unexpected increase in temperature after 450 days is the difficulties with the measurement of the power (see chapter 5.2.5). The actual power at that time was probably higher than 1800 W. After the power was switched off the temperature on the canister surface was stabilized on about 30 °C. The sensor stopped giving reliable data at the beginning of June 2005.

5.5 Deposition hole 4

5.5.1 Canister power (App. 3\page 153)

The power of the canister in hole 3 has been kept constant at 1800 W from the start 011011 until 020917, when the power was decreased with about 20 W. Some initial problems have been overcome. The power has been stepwise decreased according to Table 5-1. During the period between December 6 and December 15 the power of all canisters was switched off. After that period the power was adjusted to about 1710 W.

5.5.2 Temperature on the canister surface (App. 3\pages 154-155)

See chapter 5.2.6. The maximum measured temperature on the canister surface after the power was switched on again was 88 °C. The sensor stopped give reliable data at the beginning of April 2005.

5.6 Backfill in Section1

5.6.1 Total pressure in the backfill

Geokon (App. 4\pages 159-160)

All these sensors yielded high increase in total pressure in connection with closing of the tunnel drainage. The maximum measured pressure was about 2.5 MPa. After the opening of the drainage the total pressure was stabilized on the same level as before the closing of the drainage (maximum pressure about 0.2 MPa).

One sensor is out of order.

Kulite (App.4 \pages 161-162)

These measurements yielded rather small increase in total pressure until the drainage of the tunnel was closed. The maximum pressure recorded with PBA10013 was about 500 kPa. The sensor stopped functioning after the rapid increase in pressure when the tunnel drainage was closed but is giving reliable values again at the end of this measuring period. Sensor PBA10013 is placed 1.7 m above the bentonite surface in hole 3.

All sensors are out of order.

5.6.2 Suction in the backfill (App. 4\pages 163-169)

The suction in the backfill is measured with Wescor psychrometers. The steady but slow wetting (decrease in suction) observed in about 50% of the sensors continues. 7 sensors close to the roof and walls of the tunnel and one sensor just above the buffer in hole 1 indicate fast wetting that has gone close to water saturation (less than 1000 kPa suction). Also the sensor placed just inside the plug has reached a suction value that indicates saturation. In connection with the closing of the drainage, a very rapid decrease in suction was recorded by the installed psychrometers. Six of these sensors placed in the central part of the tunnel section yielded an increase in suction, after the reopening of the drainage, to the same level as before the closing.

Many of these sensors have stopped giving reliable values due to high water saturation of the backfill.

5.6.3 Pore water pressure in the backfill

Geokon (App. 4\pages 170-171)

All these sensors yielded high increase in pore pressure when the drainage of the tunnel was closed. Many of the sensors recorded pressures up to 2.3 MPa. After the opening of the drainage the pore pressure was stabilized at low pressures (below 0.1 MPa)

Kulite (App. 4\pages 172-173)

Also some of these sensors recorded very high water pressure after the closing of the drainage. Eight sensors are out of order.

5.6.4 Temperature in the backfill (App. 4\pages 174-178)

The temperature in the backfill ranges from 18 to 35 degrees. The highest temperature is as expected measured above the buffer in hole 3.

5.7 Temperature in the rock

5.7.1 Near hole 1 (App. 1\pages 107-109)

The maximum temperature measured in the rock is 38.6 °C. This temperature was measured with the thermocouple TROA1030 located 2.038 m from the center of the canister in deposition hole 1. The temperature in the rock close to the deposition hole decreased when the power to the canisters was switched off but increased again when the power was switched on to a temperature about 1 °C lower than before the power was switched off.

5.7.2 Near hole 2 (App. 3\page 147)

The maximum temperature in the rock (46.8 °C) was measured by TROA1820 located 2.490 m from the center of the canister in deposition hole 2 just before the power to the canisters was switched off. Since no power is applied to this canister anymore the temperature in the rock around the deposition hole is continuing to drop.

5.7.3 Near hole 3 (App. 2\pages 138-139)

The maximum temperature in the rock (48.8 °C) was measured by TROA2120 located 1.967 m from the center of the canister in deposition hole 3 just before the power to the canisters was switched off. Although the power was switched on again the temperature around the deposition hole is continuing to drop. This is most obvious for the sensors installed in the direction towards deposition hole 2.

5.7.4 Near hole 4 (App. 3\page 152)

The maximum temperature in the rock (46.5 degrees) is measured by TROA3030 located 2.034 m from the center of the canister in deposition hole 4. Also for this deposition hole there was a drop in the temperature in the rock when the power was switched off. After the power was switched on again the temperature in the rock increased to almost the same level as before the power was switched off.

5.8 Analyze of data from Section 1

5.8.1 Deposition hole 1

Before the drainage of the tunnel was closed and the power of the canister was switched off the saturation of the buffer at mid height of the canister in block R5 indicated both by the relative humidity sensors and total pressure sensors to be high even close to the canister (PBU10015). This was not changed when the drainage was opened and power of the canister was switched on again. The degree of saturation in the solid blocks both under (block C1) and above the canister (Blocks C2-C4) is much lower but a slow increase with the time of relative humidity and swelling pressure is indicated by the sensors. This trend is continuing with the same rate after the drainage was opened and the power was switched on.

In Figure 5-1 the temperature in the buffer is plotted as function of the radius from the center of the deposition hole. The measurements are made with different type of sensors in block R5 (at mid height of the canister). A straight line is fitted to the measured values. The temperature gradient is determined from the fitted line in the figure. This gradient together with the temperature on the canister surface and the temperature in the buffer close to the outer radius of the ring shaped block ($r = 785 \text{ mm}$) are plotted as function of time in Figure 5-3. The shaded part of the plot represents the time when the power to the canister was switched off at the beginning of December. The plot shows that the temperature after this is somewhat lower than before, probably due to the fact that no power is applied to canister 2 after December 2 2004. However the temperature gradient over the buffer is similar before and after the switch on/off the power of the canisters.

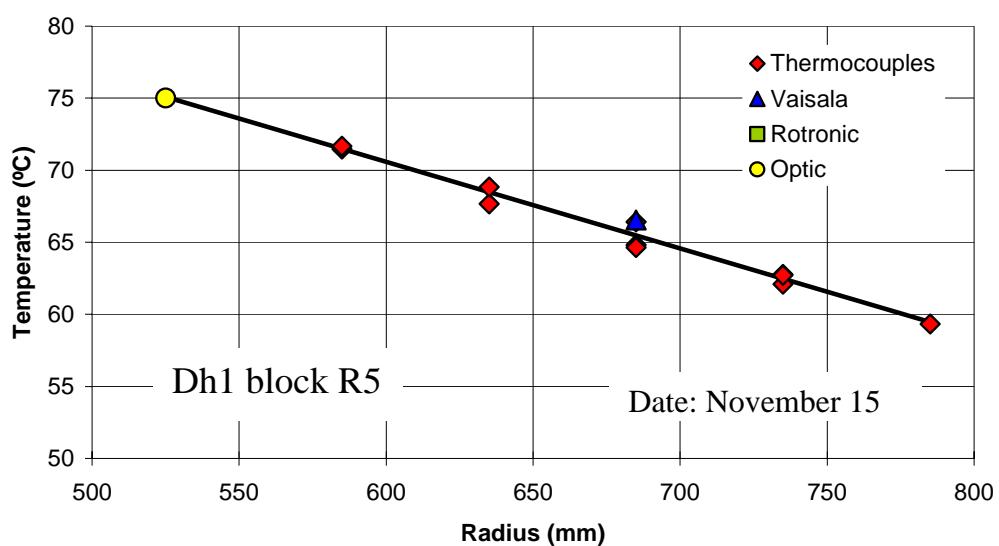

Figure 5-1. The temperature in block R5 in Dh 1 as function of radius from the center of the deposition hole on November 15, 2004.

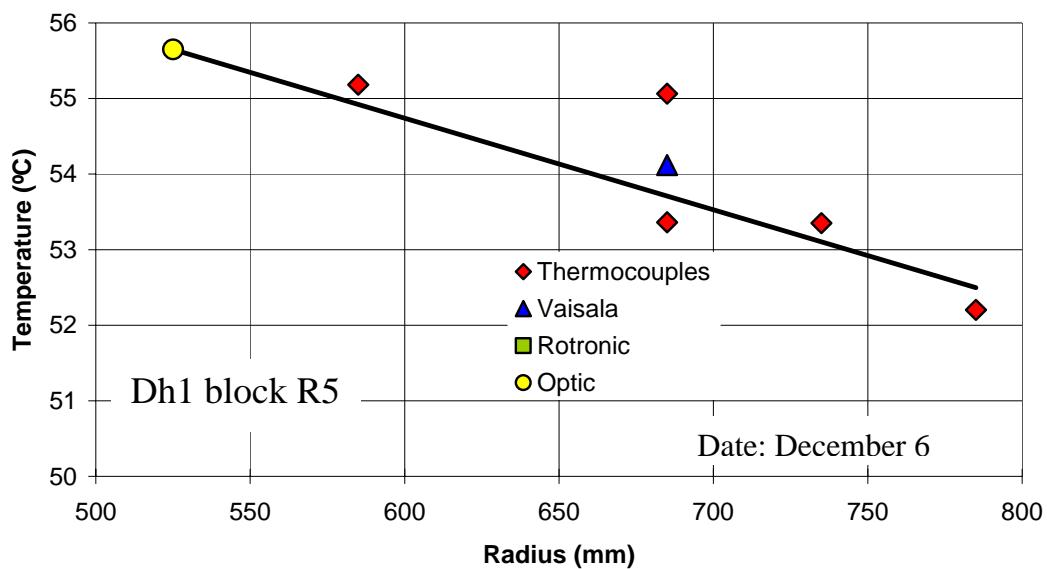

Figure 5-2. The temperature in block R5 in Dh 1 as function of radius from the center of the deposition hole on December 6, 2004.

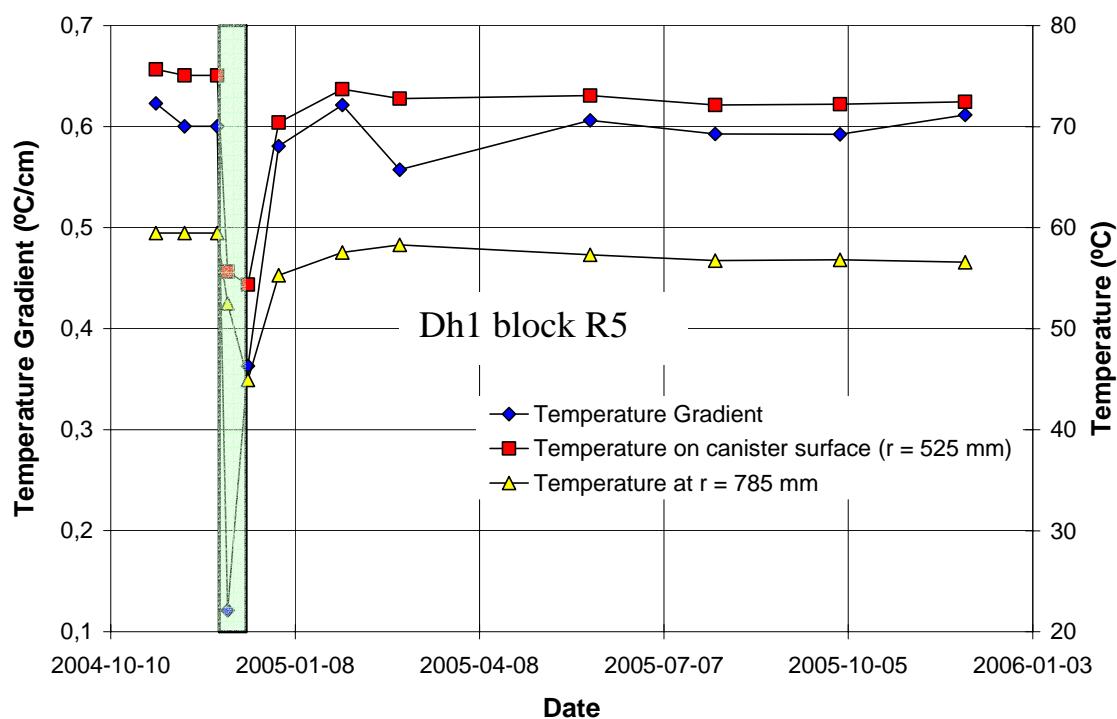

Figure 5-3. The temperature and temperature gradient plotted as function the date in deposition hole 1 block R5.

5.8.2 Deposition hole 3

The saturation of the buffer, as an average, indicated by both RH-transducers and total pressure transducers was before the closing of the drainage much lower compared to the buffer in deposition hole 1, although some total pressure transducers placed above and under the canister indicated rather high total pressures. When the drainage was closed those total pressure transducers which before had indicated high total pressure reacted with a rapid increase in pressure while the rest of the transducers did not react at all. When the drainage was opened again and the power to the canisters was switched off there was a decrease in the pressure. For most of the transducers the pressure went down to the same level as before the closing of the drainage. One RH sensor placed in block R5 at a radius of 785 mm reacted with a significant increase in RH (from 70% to 82%) when the drainage was closed. The RH was maintained on the higher level even after the opening of the drainage. Also some transducers placed in the buffer but close the canister top reacted with an increase in RH of about 5%. These transducers had before the closing of the drainage indicated a drying of the buffer. The rest of the RH transducers reacted very little at the closing/opening of the drainage.

In Figure 5-4 the temperature in deposition hole 3 is plotted as function of the radial distance from the center of the deposition hole. Compared the corresponding plot for deposition hole 1 this plot shows a significant drop in temperature between the surface of the canister and the buffer (inner diameter of the ring). This indicates that the initial slot (of about 10 mm) between the canister and the buffer was still open.

The temperature gradient over the inner slot together with the temperature on the canister and the temperature on the inner radius of the ring shaped block are plotted as function of time in Figure 5-5. The shaded part of the plot represents the time when the power to canisters was switched off. Immediately after the power was switched off the temperature gradient increased which indicate that the slot was isolating the canister resulting in a much faster drop in temperature of the buffer than the canister surface. When the power was switched on again the temperature gradient over the slot reached the same level as before the closing of the drainage indicating an open slot between the canister and the buffer, but the figure is also show that the gradient is decreasing with time which might be an indication of that the gap is getting smaller. The sensors for measuring the temperature on the canister surface stopped functioning of August 2005. The temperature gradient over the inner slot could not be calculated after that date.

The temperature gradient over the buffer is plotted in Figure 5-6 together with the temperature on the inner surface of the block and the temperature at the radius of $r = 785$ mm. After the power was switched on again also this gradient stabilized on the same level as before the power was switched off.

A conclusion of the analyses is that even though the pressure in the backfill and in the surrounding rock was high (more than 2 MPa) when the drainage was closed, water did not enter the inner slot between the buffer and the canister. The fact that no water pressure acted directly on the canister surface can also explain the large vertical displacement of the canister measured when the drainage was closed (see Figure 5-7). If the increased pore pressure (2.5 MPa) would act directly on the canister surface the deformation should be much smaller than what was measured. The measured deformation was probably caused by large deformations of the solid bentonite blocks on top and bottom of the canister.

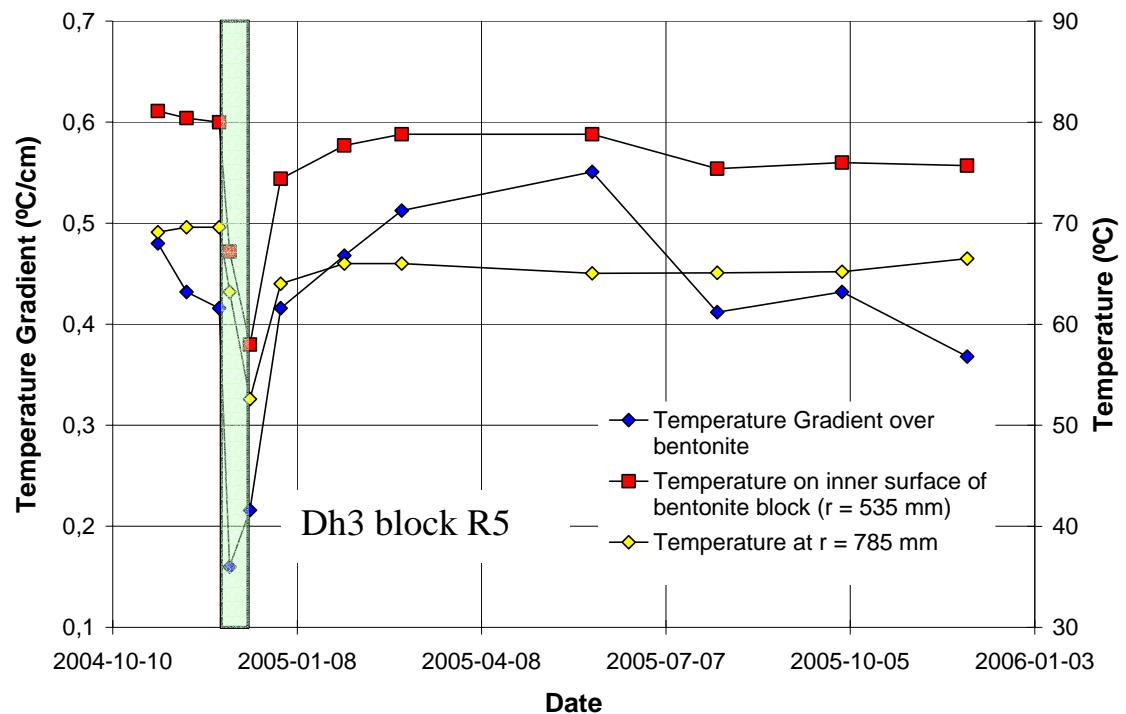

Figure 5-6. The temperature and temperature gradient over the buffer plotted as function the date in deposition hole 3 block R5.

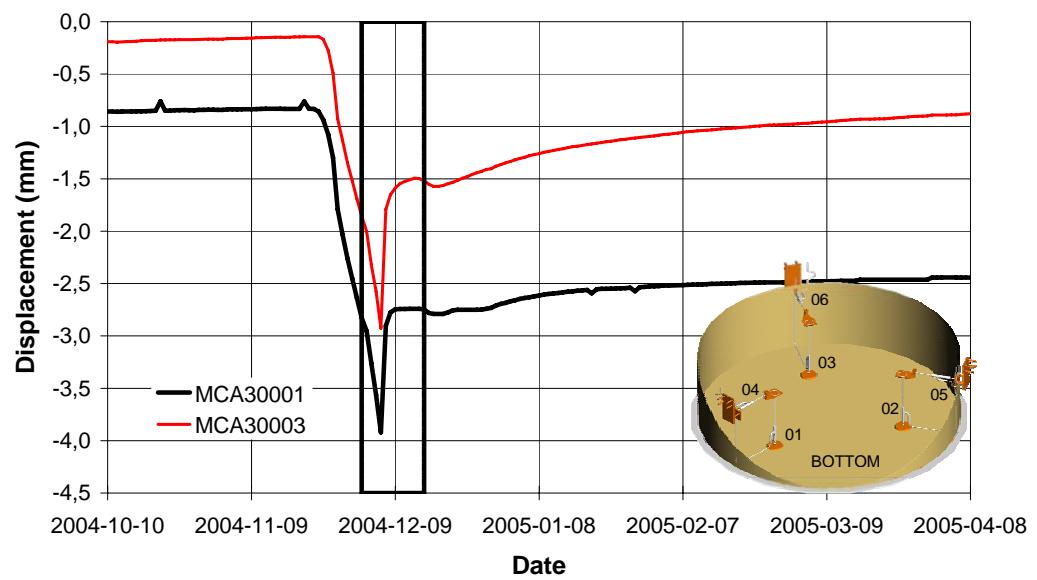

Figure 5-7. Vertical displacement of the canister in Dh 3. Negative sign on the displacement means that the canister is moving downwards.

5.8.3 Backfill

The pore pressure in the backfill increased fast from a low level when the drainage of the tunnel was closed. This affected the rate in which the backfill was saturated measured both with soil psychrometers and with resistivity measurements made by GRS. After drainage was reopened the pore pressure stabilized on the same level as before it was close. The saturation rate (measured with both psychrometers and resistivity measurements) decreased to the same rate as before the closing of the drainage for most of the sensors.

6 Location of instruments in Section 2

6.1 Strategy for describing the position of each device in the bentonite and rock in and around the deposition holes

The deposition holes in Section 2 are termed DA3551G01 and DA3545G01, hole number 5 and 6 respectively according to Figure 1-1.

Deposition hole 5 has been instrumented in the same way as the two inner deposition holes, 1 and 3 i.e. measurements have been done in four vertical sections A, B, C and D according to Figure 4-1. (See chapter 4-1)

Deposition hole 6 has, however, been instrumented according to another strategy. The instruments have been placed in eight directions, where four directions are represented in each instrumented block, see Figure 6-1.

Direction A and C are placed in the tunnels axial direction with A headed against the end of the tunnel i.e. almost to the West, see Figure 2-1.

Every instrument placed in the buffer is named with a unique name consisting of 1 letter describing the type of measurement, 1 letter describing where the measurement takes place (buffer, rock), 1 figure denoting the deposition hole (5-6) and 2 figures specifying the instrument according to separate lists (see Table 6-1 to 6-11). Every instrument position is then described with three coordinates according to Figure 2-1.

The bentonite blocks are called cylinders and rings. The cylinders are numbered C1-C4 and the rings R1-R10 respectively, see Figure 4-1.

Thermocouples in the rock are placed on 3 levels in each deposition hole (bottom, 3 m and 6 m level). Thermocouples are placed in the bottom of the deposition holes in a vertical hole at the center of the deposition hole. On level 3 m and 6 m the thermocouples are placed in two vertical directions perpendicular to each other.

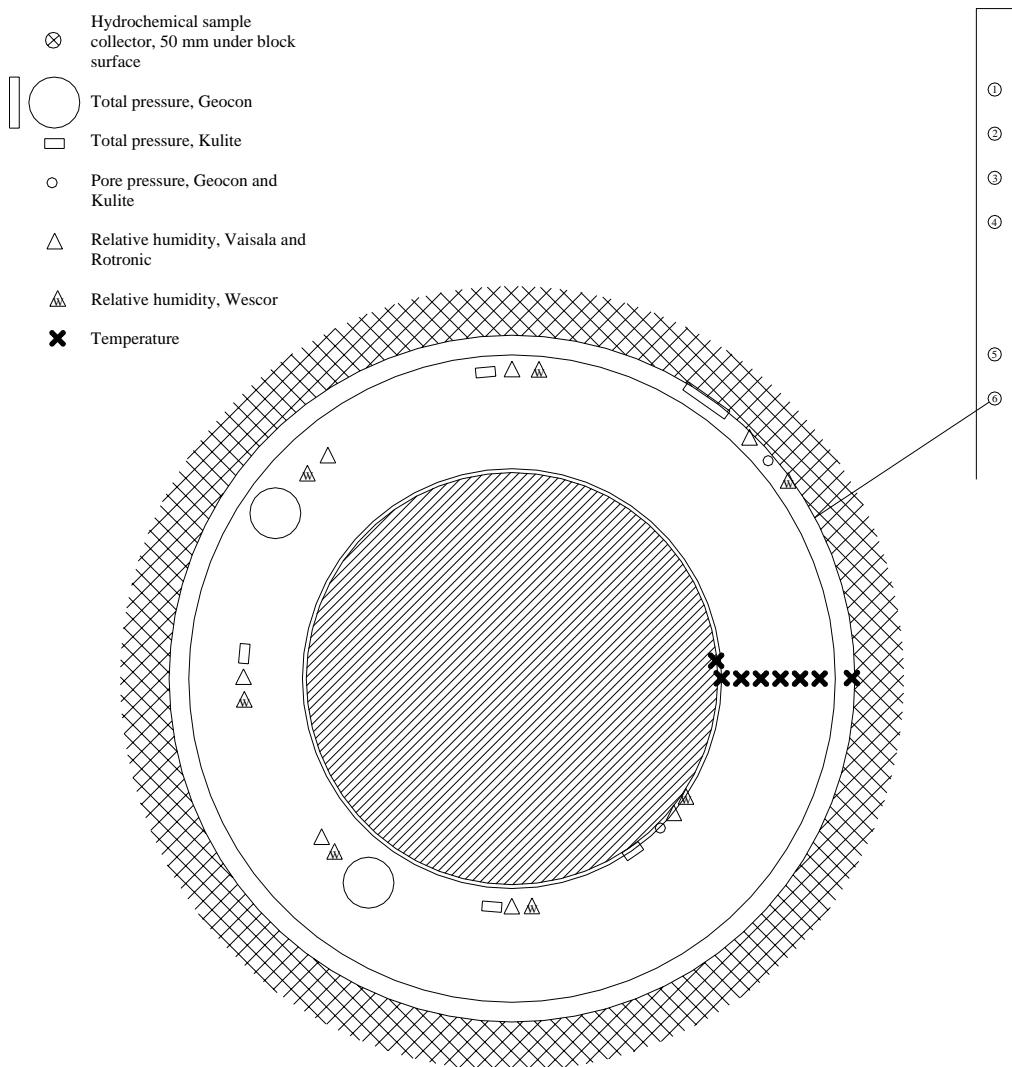

Figure 6-1. Schematic view over the instruments positions in deposition hole 6. The instruments are placed in eight vertical sections, where four sections are represented in each instrumented block.

6.2 Position of each instrument in the bentonite in hole 5 (DA3551G01)

The instruments are located according to the same system as those in hole 1 and hole 3.

The positions of each instrument are described in Tables 6-1 to 6-4. These tables have been updated since the last data report (Sensors data report No 7).

The positions of 10 Wescor psychrometer sensors were determined after inflow measurement on the wall of the deposition hole. The position of these sensors are described in Table 6-5

Table 6-1 Numbering and position of instruments for measuring temperature (T) in the buffer in hole 5.

6.3 Position of each instrument in the bentonite in hole 6 (DA3545G01)

The instruments are located in one main level in the blocks, 250 mm, from the upper surface. The upper blocks, C2, C3 and C4 are instrumented in the same way as those in deposition hole 5. The positions of each instrument are described in Tables 6-6 to 6-9. These tables have been updated since the last data report (Sensors data report No 7).

The position of 10 Wescor psychrometers and 5 Vaisala relative humidity sensors were determined after inflow measurement. The positions of these transducers are described in Table 6-10.

6.4 Instruments on the canister surface in holes 5-6

A system for measuring the temperature with optical cables on the surface of the canisters is used in the same way as for the canisters in Section 1. The system is described in chapter 4.4.

In additional to the optical cables three thermocouples (TB504, TB511 and TB524) in deposition hole 5 and three thermocouples (TB611, TB619 and TB627) in deposition hole 6 are fixed to the surface of the canister (see Table 6-1 and 6-6).

6.5 Position of temperature sensors in the rock

Thermocouples are placed on 3 levels in each deposition hole (bottom, 3 m and 6 m level). On level 3 m and 6 m the thermocouples are placed in two directions perpendicular to each other.

The positions are described in Table 6-11.

Table 6-11. Numbering and position of temperature sensors in the rock.

6.6 Strategy for describing the position of each device in the backfill in section 2

The strategy for instrumentation of the backfill in Section 2 is the same as in Section 1 and is described in chapter 4.6.

6.7 Position of each instrument in the backfill in Section 2

The positions of each instrument are described in Tables 6-12 to 6-15.

Table 6-12 Numbering and position of instruments for measuring temperature (T) in the backfill in section 2.

7 Results and comments for Section 2

7.1 General

In this chapter short comments on general trends in the measurements are given. Sensors that are not delivering reliable data or no data at all are noted and comments on the data collection in general are given.

The heating of the canister in hole 5 started with an applied constant power of 1800 W at 030508. This date is also marked as start date. The backfilling started 030429 and was finished 030625 and the plug was cast at 030911. Table 7-1 shows some important dates for section 2.

Table 7-1. Key dates for section 2

Activity	Date
Start backfilling	29/4 2003
Start heating canister 5	8/5 2003
Start heating canister 6	23/5 2003
Finished backfilling	25/6 2003
Plug casting	11/9 2003
Decreased power (-30 W)	8/9 2004
The power to all canisters was switched off	2/12 2004
The drainage of the tunnel was opened	6/12 2004
The power to the canisters was switched on	15/12 2004
The power to canister 6 was switched off	6/9 2005
The power to canister 6 was switched on	2/11 2005

84 out of 394 sensors (excluding water pressure sensors in the rock, geo-electric measurements, stress and strain in the rock and displacement of canister) are out of order.

The processes have been slow up to about 20 days after the drainage of the tunnel was closed. Very small changes of the measured parameters have occurred up to that date. After that the readings from some of the total and pore pressure sensors placed in the buffer have reacted strongly (quick increase in pressure). Also the total and pore pressure sensors placed in the backfill have recorded high pressures caused by the closing of the drainage. After the opening of the drainage of the tunnel, both the pore pressures and the total pressures were stabilized on a higher level than before the closing of the drainage.

The maximum measured temperature on the canister in deposition hole 5 is about 84 °C. For the canister in deposition hole 6 the maximum temperature is about 88 °C.

7.2 Deposition hole 5

7.2.1 Total pressure

Geokon (App. 5\pages 181-184)

The measured pressure range is from 0 to 9 MPa. PB506 placed in block C1 shows a strong increasing of the total pressure since day 200. High pressures are also indicated by sensors in block R5 and R10. PB511 in block R5 showed a very quick increase in pressure from day 520 up to the day when the power was switched off. After that a drop in pressure of 2 MPa was observed. Two sensors placed in block R10 (PB521 and PB522) showed a drop in total pressure at around day 300 and then they were stabilized on a pressure of about 2 MPa. These two sensors measured an increase in pressure when the drainage was closed. When the power to the canister was switched off the pressures measured with these sensors decreased quickly with about 2 MPa. After the power was switched on again the measured pressures increased to the same level as before the power was switched off. The measured pressures are continuing to increase.

Three sensors are out of order.

Kulite (App. 5\page 185)

The highest pressure 1.2 MPa is measured by a peripheral sensor in block R10. Sensor PB519, also placed in block R10 but closer to the canister shows a pressure of 0.70 MPa. A sensor (PB510) placed in the peripheral of block R5 measure a total pressure close to 0.90 MPa. The rest of the sensors measure low pressures.

Two sensors are out of order.

7.2.2 Relative humidity/suction in dep. hole 5

Vaisala (App. 5\pages 186-189)

Since temperature is also measured with all relative humidity sensors, the diagrams include those measured temperatures. The temperature measurements start at about 16 degrees while the RH measurements start at about 70 % RH.

The sensors placed in the bottom block C1 show very small changes in RH with time.

One sensor placed in block R5 close to the canister (WB519) indicated a very strong drying of the bentonite until day 170 when it stopped to give reliable values. Sensor WB520 placed in the middle of block R5 indicated also an initial drying of the bentonite. The rest of the sensors in block R5 indicate a slowly wetting of the buffer (increase in RH).

Two sensors in block R10 placed close to the top of the canister (WB522, WB523) indicated a drying of the bentonite up to day 350 and after that a slowly wetting. The rest of the sensors in block R10 indicate a wetting of the buffer.

Three sensors placed in block C3 and C4 indicate a slowly wetting of the buffer.

Eight sensors are out of order.

Rotronic (App. 5\pages 190-194)

Five of the sensors placed in the bottom block C1 show very small changes in RH with the time, while three sensors (WB508, WB509 and WB511) indicate a slow wetting of the bentonite.

One sensor placed in block R5 close to the canister (WB516) indicated a very strong drying of the bentonite for the first 60 days. The sensor indicated then a wetting for the next 60 days and after that another period of drying until day 230. After that the sensor is measuring an increase in Relative Humidity indicating a wetting of the buffer.

One sensor placed in block C3 indicates a slowly wetting of the bentonite.

Six sensors are out of order.

Wescore Psychrometers (App.5\page 195)

The Wescor sensors can measure suction between 6000 and 200 kPa.

Two of totally five sensors are beginning to measure a decrease in suction of the buffer. These sensors (WB358 and WB542) are placed near the periphery of block R3.

7.2.3 Pore water pressure

Geokon (App. 5\page 196)

All sensors yield very low pressures.

Kulite (App. 5\page 197)

Sensors UB508 was out of order from start and it is not plotted in this report.

All the installed sensors yield very low pressure.

Three sensors are out of order.

7.2.4 Temperature in the buffer (App. 5\pages 198-207)

Three thermocouples (TB504, TB511 and TB524) are placed on the surface of the canister. TB504 placed closed to the bottom of the canister shows a maximum temperature of about 70 °C , TB511 placed at the middle of canister about 77 °C and TB524 placed close to the top of the canister shows a maximum temperature of about 70 °C.

High temperatures are measured with thermocouples placed in the center of block C1 and just below the canister (TB503, 69 °C) and in block R5 (TB513, 74 °C). The temperature gradient over block R5 (between the radius 585 mm and 785 mm) at the end of this measuring period is 0.70 °C/cm.

The temperature in the buffer is also measured with the Geokon sensors. The maximum temperature recorded with these sensors is about 70 °C at the end of this measuring period (PBU502 placed in the center of block C1 close to the canister).

The temperature in the buffer is also measured with the Wescor sensors. The maximum temperature recorded with these sensors is about 72 °C at the end of this measuring period.

7.2.5 Canister power (App. 5\page 213)

The power of the canister in hole5 has been kept constant at 1800 W from the start 2003-05-08 until the beginning of September 2004 when the power was decreased to about 1770 W. During the period between December 6 (day 575) and December 15 (day588) the power to the canister was switched off. After that period the power was adjusted to about 1770 W again.

Due to problems with the data collection system, data is missing for the first 45 days of the heating.

7.2.6 Temperature on the canister surface (App. 5\pages 214-216)

The first diagram shows the maximum temperature, measured with the optical cables placed on the surface of the canister, plotted as function of time. The present maximum measured temperature on the canister surface is about 80 °C. The second diagram shows the distribution of the temperature along the optical cables at the end of this measuring period. With no damages on the optical cables this plot should have four curves. Only two curves with relevant values are presented here which indicates that the optical cables are damaged. The length of the cables on the canister surface is about 20 m. The variation of a few degrees is caused by the difference in temperature at the center and ends of the canister. The curves may thus be further corrected after completed calibration. Compared to the measurements of the canister temperature with conventional thermocouples (see chapter 7.2.4) the optical cables yield a higher maximum temperature

7.3 Deposition hole 6

7.3.1 Total pressure

Geokon and Kulite (App. 6\pages 219-222)

The results from two types of sensors are presented in the same plot.

The measured pressure range is from 0 to 10 MPa. Two sensors, PB624 and PB627 placed in the top block (C4) showed an increase in pressure with about 1.5 MPa when the drainage of the tunnel was closed. Three sensors placed in Block R1 and R2, PB603, PB606 and PB607, showed a strong increase in pressure during the whole measuring period. Sensor PB607 showed a quick increase in pressure after the power was switched on again. Three sensors placed in Block R8 and R9, PB620, PB621 and PB623, showed a strong increase in pressure after the power was switched on again. All the sensors reacted also with a rapid decrease in pressure when the power to canister 6 was switched off for the second time. After the drop in pressure most of the sensors started to measure an increase in pressure even though the power was not switched on.

Nine sensors (eight Kulite and one Geokon) are out of order.

7.3.2 Relative humidity/Suction

Vaisala and Rotronic (App. 6\pages 223-229)

The results from two types of sensors are presented in the same plot.

The sensors placed in the bottom block C1 show very small changes in RH with the time.

Two sensors placed in block R1 and R2 indicated a very quick increase in RH when the drainage was closed.

One sensor in block R6 reacted strongly after the drainage was closed.

One sensor placed close to the canister in block R9 (WB645) indicates a drying of the buffer. The rest of the sensors in block R8 and R9 indicate a slowly wetting of the buffer up to the closing of the drainage. At that point a quick increase in RH was measured by several sensors.

Two sensors (WB649, WB650) placed in block R10 and at the top of the canister indicated an initial wetting of the bentonite and then a continuing drying.

The sensors placed in block C3 and C4 show very small changes in RH with the time.

Sensors WB606, WB634 and WB648 were out of order at the start of the heating phase and are not plotted in this report.

30 of the initial 37 installed sensors are out of order, some of them due to data logger problems.

Wescore Psychrometers (App. 6\page 230-234)

Three of totally nine sensors installed in the rock wall are measuring suction in the rock at the end of this measuring period. Seven of totally 26 sensors installed in the buffer are beginning to measure a decrease in suction in the buffer.

7.3.3 Pore water pressure

Geokon and Kulite (App. 6\pages 235-237)

All sensors except one yield very low pressures (below 0.2 MPa) One sensor placed in block R6 close to the outer radius of the block shows a pressure of about 0.45 MPa at the end of this measuring period.

Four sensors (Kulite) are out of order.

7.3.4 Temperature in the buffer (App. 6\pages 238-251)

Three thermocouples (TB611, TB619 and TB627) are placed on the surface of the canister. TB611 placed closed to the bottom of the canister showed a temperature at the end of this measuring period of about 58 °C while TB619 placed at the middle of canister showed a temperature of 66 °C. TB627 placed close to the top of the canister was measuring a temperature of 64 °C.

The maximum temperature in the buffer recorded at the end of this measuring period is 66 °C. It was measured in block R5, close to the canister (TB612). The temperature plot for this sensor indicates that it is in contact with the canister. When this sensor is excluded the maximum temperature gradient over block R5 is about 0.52 °C/cm. The thermo couples placed close to the canister are giving significant lower values after the switch off/switch on of the power to the canister.

Eleven thermocouples are out of order.

The temperature in the buffer is also measured by the installed Geokon sensors. The maximum temperature recorded with these sensors at the end of this measuring period is about 64 °C (UB609 placed in block R2 close to the canister). Two sensors are out of order.

The temperature in the buffer is also measured with the Wescor sensors. The maximum temperature recorded with these sensors is about 65 °C at the end of this measuring period.

7.3.5 Canister power (App. 6\page 255)

The power of the canister in hole 6 has been kept constant at 1800 W from the start 2003-05-08 to the beginning of September 2004 when the power was decreased to about 1770 W. During the period between December 6 (day 575) and December 15 (day 588) the power to the canister was switched off. After that period the power was adjusted to about 1770 W. During a period of about 2 months (from August 2) the power was switched off again and after that the power was adjusted to 1770 W again.

Due to problems with the data collection system, data is missing for the first 30 days of the heating.

7.3.6 Temperature on the canister surface (App. 6\pages 256-258)

The first diagram shows the maximum temperature plotted as a function of time. The average maximum measured temperature on the canister surface at the end of this measuring period is about 70 °C. The second diagram shows the distribution of the temperature along the optical cables at the end of this measuring period. The maximum temperature has decreased with about 9 °C after the switch off/switch on of the power at the end of year 2004. The temperature has not fully recovered from the latest period when the power was switched off. With no damages on the optical cables this plot should have four curves. Only two curves with relevant values are available which indicates that the optical cables are damaged. The length of the cables on the canister surface is about 20 m. The variation of a few degrees is caused by the difference in temperature at the center and ends of the canister. Compared to the measurements of the canister temperature with conventional thermo couples (see chapter 7.3.4) the optical cables yield a higher maximum temperature.

7.4 Backfill in Section 2

7.4.1 Total pressure

Geokon (App. 7\page 261)

All the total pressure sensors measured an increase in pore pressure, of about 1 MPa, after the drainage of the tunnel was closed. The highest total pressures before the closing of the drainage, 400 kPa, was measured by the sensor PFA13. This sensor is placed just above the bentonite surface in the deposition hole 6. The rest of the total pressure sensors measured very small pressures before the closing of the drainage. However, all installed sensors indicated an increase in pressure when the drainage was opened again. The maximum measured pressure after the closing of the drainage was about 0.4 MPa. Just before the power to canister 6 was switched off again at the beginning of September 2006 the maximum recorded pressure was about 1 MPa. The maximum decreased to about 0.6 MPa after the power was switched off. The maximum pressure at the end of this measuring period is about 0.8 MPa.

Kulite (App. 7 \page 262)

These sensors measured also an increase in total pressure of about 1 MPa due to the closing of the drainage. The highest pressure before the closing of the drainage was measured by the sensor PFA12, about 0.4 MPa. This sensor is placed just above the bentonite surface in deposition hole 6. The rest of the total pressure sensors measured very small pressures before the closing of the drainage. After the reopening of the drainage the sensors measured a maximum pressure of about 1 MPa. When the power to canister 6 was switched off again at the beginning of September 2006 the maximum recorded pressure decreased to 0.6 MPa. The maximum pressure at the end of this measuring period is about 0.8 MPa.

7.4.2 Suction (App. 7 \pages 263-269)

The suction in the backfill is measured with Wescor psychrometers. Most of the psychrometers yield suction values between 2500 and 3500 kPa at the start of the test, which correspond to the initial suction at a water ratio in the backfill of 12%. Some sensors have clearly been wetted to almost full saturation (suction below 1500 kPa) very short after the start of the test. These sensors (WFA12, WFA20, and WFA27) are placed close to the rock surface. A decrease in suction and thus a wetting of the backfill was indicated by the rest of the sensors until the closing of drainage of the tunnel. All of the still working sensors were after this event showing a quicker decrease in suction. Only one of the installed sensors is still yielding reliable values.

The position of WFA14 is not clear and the sensor is not plotted in this report.

7.4.3 Pore water pressure

Geokon (App. 7\pages 270-272)

All the sensors, except one (UFA11), showed an increase in pore pressure, about 1 MPa, after the closing of the tunnel drainage. Before this event the sensors recorded very low pressures. After the drainage was reopening all sensors placed close to the tunnel

surface indicated an increasing pore pressure. Just before the power to canister 6 was switched off again at the beginning of September 2006 the average recorded pressure was 0.5 MPa. The pressure dropped then with about 0.2 MPa. The average pressure for these sensors at the end of this measuring period was 0.3 MPa.

Kulite (App. 7\page 273)

Three of the sensors showed an increase in pore pressure, about 1 MPa, after the closing of the tunnel drainage. Before this event the sensors recorded very low pressures. After the drainage was reopened again, the two still working sensors measured maximum values of about 0.55 MPa. When the power to canister 6 was switched off again the pressures dropped with about 0.2 MPa. The sensors are measuring pressures of about 0.4 MPa at the end of this measuring period.

Two sensors are out of order.

7.4.4 Temperature (App. 7\pages 274-276)

The temperature in the backfill ranges from 19 to 30 °C. The highest temperatures is as expected measured above the buffer in hole 5. When the power to canister 6 was switched off at the beginning of September 2006 the temperature in the backfill close to canister in deposition hole 6 dropped with about 2°C.

7.5 Temperature in the rock

7.5.1 Near hole 5 (App. 5\pages 208-212)

The maximum temperature in the rock (54 °C) is measured by TROA5055 located at rock surface near the center of the canister in deposition hole 5.

Six sensors show suddenly increase in temperature with (2 degree) probably due to data logger problems during a period of about 100 days.

7.5.2 Near hole 6 (App. 7\pages 252-254)

The maximum temperature in the rock (54 °C) was measured by TROA6055 just before the power to canister 6 was switched off. The sensor is located at rock surface near the center of the canister in deposition hole 6. All the sensors placed close to deposition hole 6 measured a drop in temperature when the power was switched off and have not reached the same level as before, at the end of this measuring period.

7.6 Analyze of data from Section 2

7.6.1 Deposition hole 5

The saturation of the buffer in deposition hole 5 indicated by both RH sensors and total pressure sensors is complex. Some total pressure sensors indicate rather high total pressures (higher than 2.5 MPa) while others measure very low pressures. The sensors giving high pressures are placed both in block C1, R5 and R10. Common for all the

sensors is that they are placed in direction A to B in the deposition hole (south- west direction). Also those RH-sensors measuring relative humidity of ~100% are placed in this direction. In other parts of the buffer most of the sensors (both RH-sensors and total pressure sensors) indicate a slow wetting of the buffer with time. Although the sensors reacted rather strongly just before and after the power was switched on and off at the beginning of December 2004, the saturation rate indicated by the sensors is not changed radically over the time. One sensor (PB510), measuring the total pressure in block R5 at the inner slot towards the canister, measured at the end of this measuring period (day 940) a pressure of about 900 kPa. This sensor started to react around day 200 which might be an indication of the time when the inner slot was closed.

In Figure 7-1 the temperature for deposition hole 5 is plotted as function of the radial distance from the center of the deposition hole at mid height of the canister. Compared to the corresponding plots for deposition hole 3 these plots do not show a drop in temperature between the surface of the canister and the buffer (inner diameter of the ring) although the temperature gradient is higher close to the canister surface. The temperature on the canister surface is also much lower compared to canister 3. These measurements indicate that the initial slot between the buffer and the canister of about 10 mm is not present anymore, but the closing of the slot is not associated with the high pressures generated in the buffer and backfill at the closing of the tunnel drainage.

The temperature gradient over the inner part of the buffer together with the temperature on the canister and the temperature at the radius of 600 mm in the ring shaped block R5 are plotted as function of time in Figure 7-2. The shaded part of the plot is representing the time when the power to the canisters was switched off. The plot shows that both the temperature and the temperature gradient were affected very little by the switch off/on of the power.

The temperature gradient over the outer part of the buffer is plotted in Figure 7-3. After the power was switched on again also this gradient stabilized on the same level as before the power was switched off.

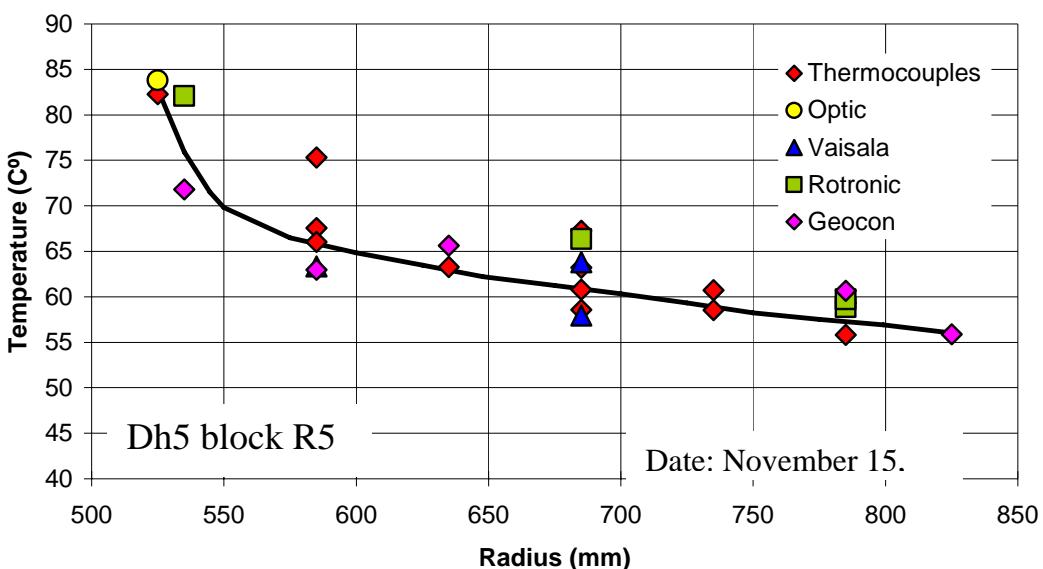

Figure 7-1. The temperature in block R5 in Dh 5 as function of radius from the center of the deposition hole on November 15, 2004.

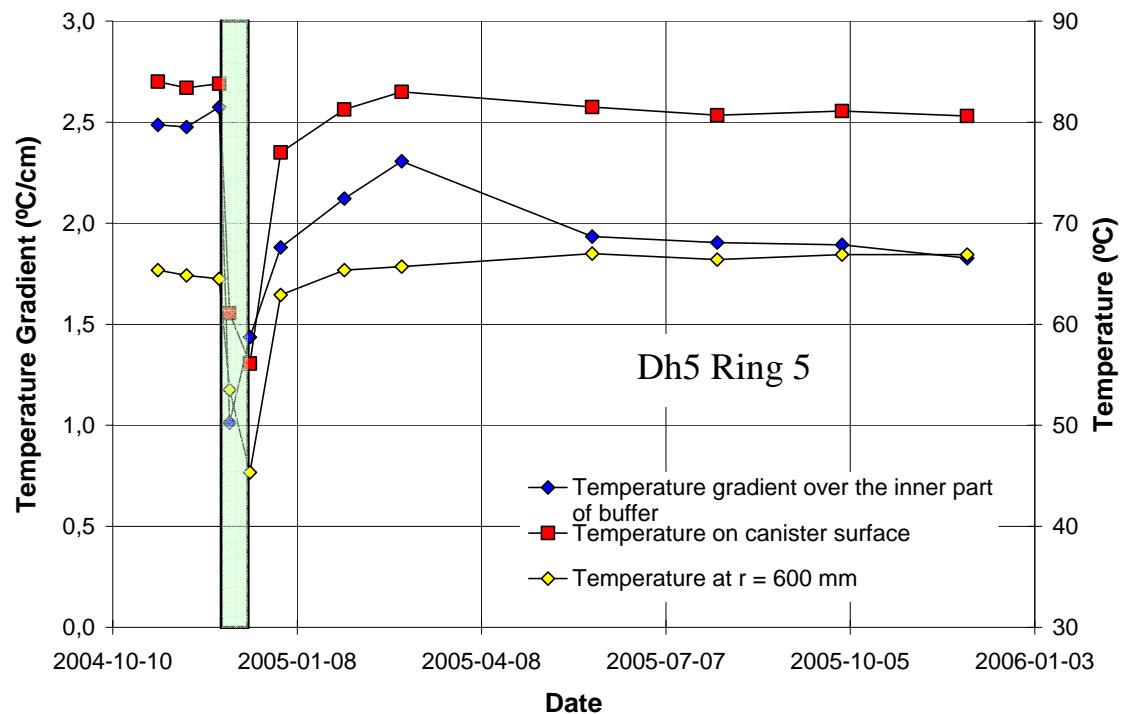

Figure 7-2. The temperature and temperature gradient over the inner par of the buffer plotted as function the date in deposition hole 5 block R5.

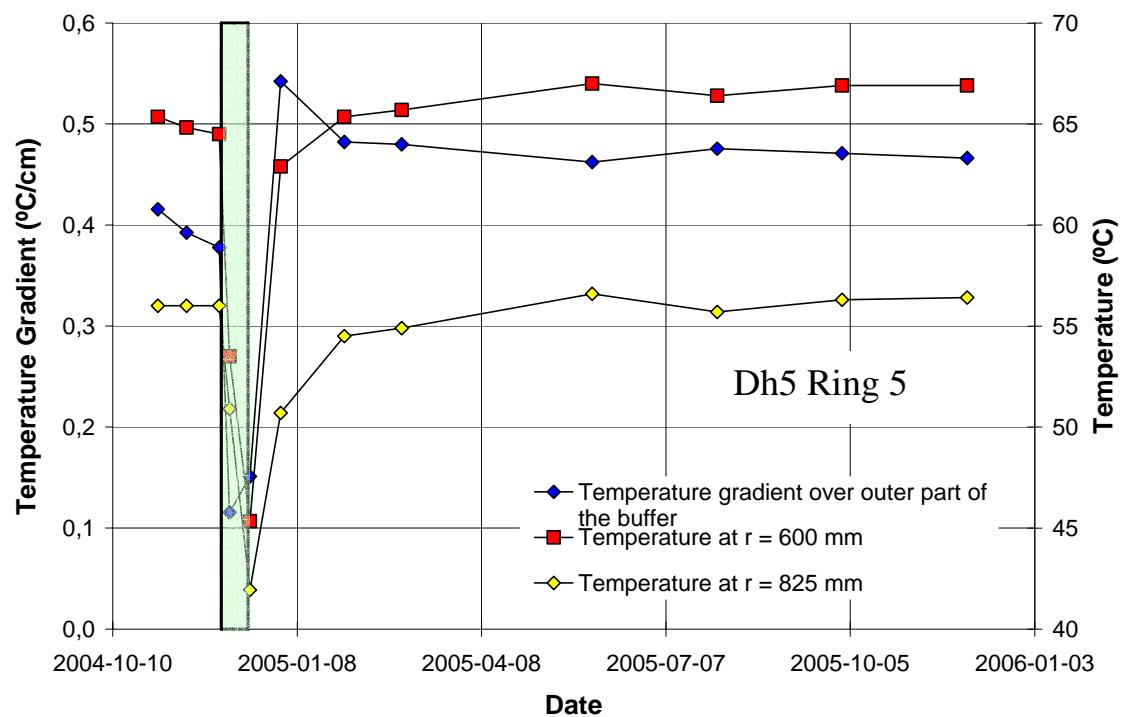

Figure 7-3. The temperature and temperature gradient over the outer par of the buffer plotted as function the date in deposition hole 5 block R5.

7.6.2 Deposition hole 6

The saturation of the buffer in deposition hole 6 was affected by the quick increase in pressure when the drainage of the tunnel was closed as indicated by both RH sensors and total pressure sensors. The total pressure was also affected when the power was switched off again at the beginning of September 2005. The drop in total pressure was very large and rapid and the pressure started to increase before the power to the canister was switched on again. When the power was switched on pressure increased very fast to the same level as before the power was switched off. This course of events is indicating that the change in total pressure is an affect of the changes in water volume in the bentonite caused by the variation in temperature.

The temperature in the buffer for deposition hole 6 is plotted as function of the radial distance from the center of the deposition hole at mid height of the canister in Figure 7-4 at November 15, 2004 which was before the high pore pressure in the tunnel was observed. Compared to the corresponding plots for deposition hole 5 these plots indicate a drop in temperature between the surface of the canister and the buffer (inner diameter of the ring). The temperature on the canister surface measured with the optical system is also much higher compared to canister 3. These measurements indicate that the initial slot between the buffer and the canister of about 10 mm was still open when the drainage was closed. Corresponding plot (Figure 7-5) some time after the drainage was opened again shows that the temperature on the surface of the canister has dropped with about 10 °C.

The temperature gradient over the inner slot is shown in Figure 7-6 as function of time. The shaded parts of the plot represents the time when the power to the canister was switched off. The plot shows that both the temperatures and the temperature gradient were affected very much by the closing/opening of the drainage which is indicating that the inner slot was closed when water entered the slot. The temperatures and the gradient were also affected when the power to the canister was switched off for the second time. Both the temperatures sand the gradient are approaching the same levels at the end of this measuring period as before the power was switched off.

The closing of the gap is also affecting the temperature development in different part of the buffer since the relation between the heat leaving the end parts of the canister and the heat leaving the cylindrical part of the canister was changed when the gap was closed. Directly after the installation the buffer was in good contact with the ends of the canister while the slot was isolating the rest of canister surface from the buffer. When the gap was closed, more of the generated heat was leaving the cylindrical part of the canister resulting in a higher temperature in the buffer at the central part of the deposition hole and a lower temperature in the buffer at the ends of the canister.

The temperature gradient over the outer part of the buffer is plotted in Figure 7-7. This gradient was also affected when the power was switched off. After the power was switched on again this gradient was stabilized on the same level as before the power was switched off.

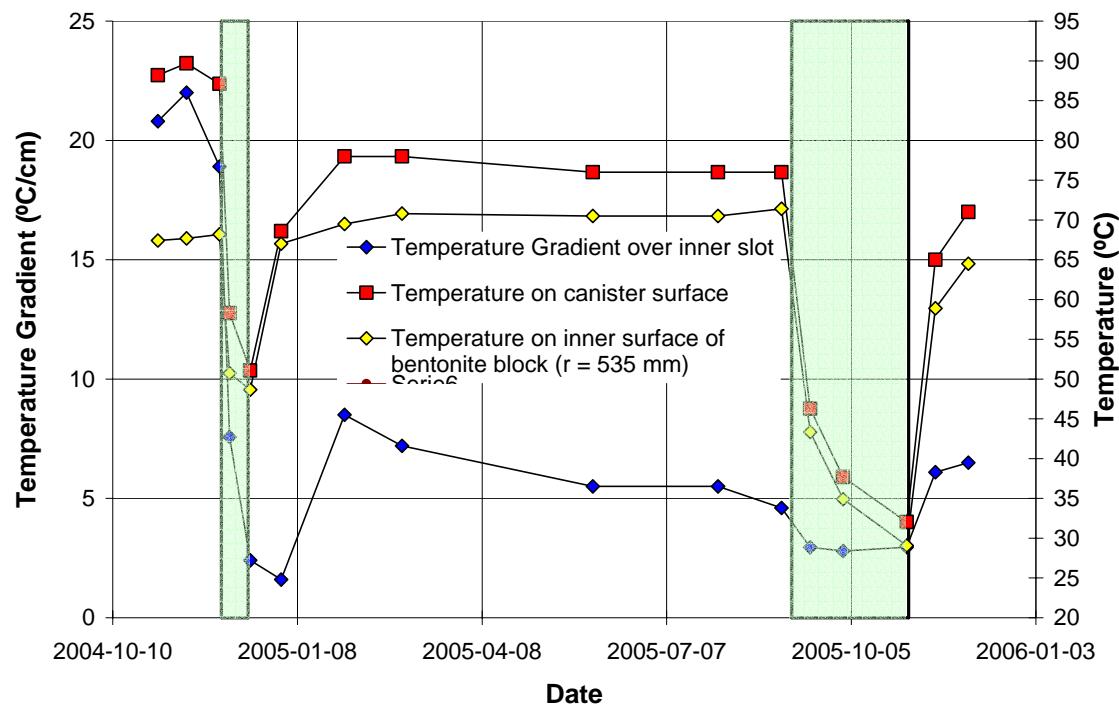

Figure 7-6. The temperature and temperature gradient over the inner slot plotted as function the date in deposition hole 6 block R5.

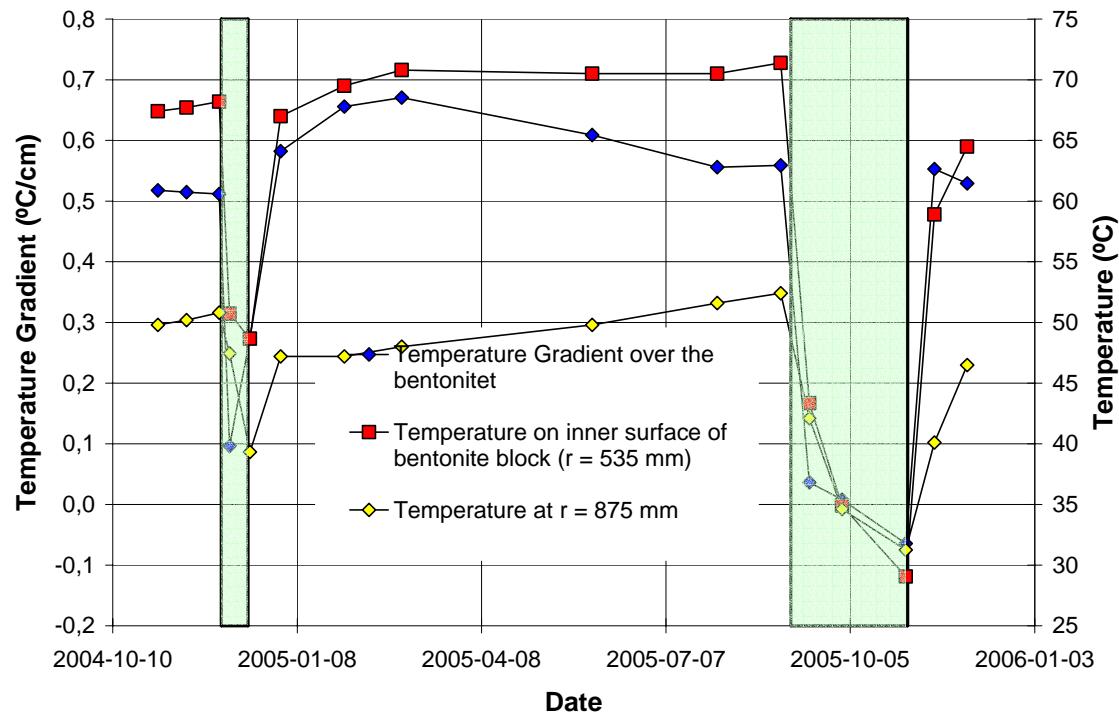

Figure 7-7. The temperature and temperature gradient over the buffer plotted as function the date in deposition hole 6 block R5.

7.6.3 Backfill

The pore pressure, measured both with total and pore pressure transducers placed in the backfill, increased fast from a low level when the drainage of the tunnel was closed. This affected the rate in which the backfill was saturated measured both with soil psychrometers and with resistivity measurements in the backfill. After the drainage was opened again the pore pressure stabilized on a higher level than before the drainage was closed. Most of the installed soil psychrometers measure very low suction values after the closing/opening of the drainage which indicates that the backfill is close to fully saturated.

1 Layout

The measurement of displacements is carried out in Section 1 on the canister in deposition hole 3. In Section 2 the displacements are measured on the canister in deposition hole 6. In deposition hole 3 six sensors are grouped into one measuring section, while in deposition hole 6 there are two measuring sections, at the bottom and on top of the canister, as shown in Figure 1.

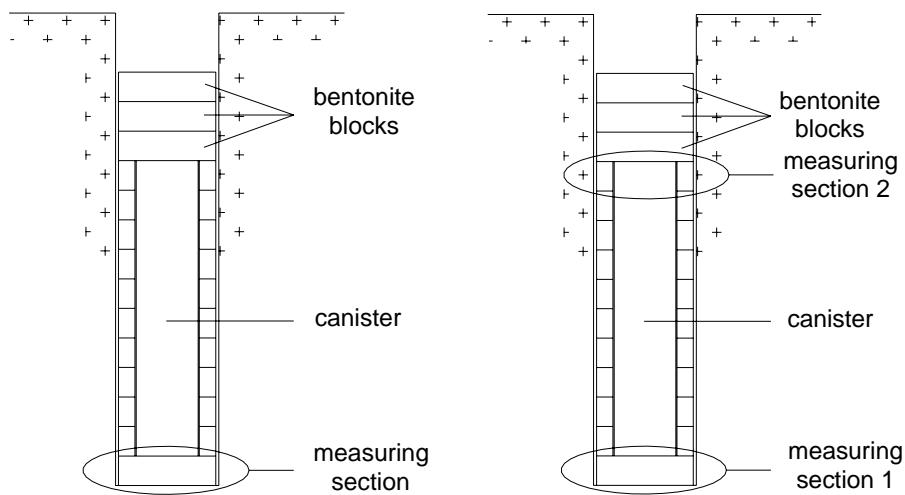

Figure 1. Location of measuring sections for deposition hole 3 (left) and deposition hole 6 (right)

For deposition hole No. 3 three sensors, named MCA30001 to MCA30003, have been placed in vertical position into holes drilled into the bottom bentonite block. These three sensors determine the vertical displacement of the canister, as well as any possible tilt. The points where the sensors are attached to the canister are the same as for the horizontal sensors.

The other three displacement sensors for deposition hole 3, named MCA30004 to MCA30006, are placed horizontally at the top of the lower bentonite block, close to the lower lid of the canister and attached to it, in a 120° radial disposition. Thus, the sensors will be always in a horizontal position, so that the horizontal displacement of the canister can be measured. The sensors have been placed so as to avoid interfering with other sensors installed in the block. Figure 2 illustrates the position of the six sensors.

For deposition hole 6 three sensors, named MC6001 to MC6003, have been placed in vertical position in the same way as for deposition hole 3. The horizontal sensors, named MCA6004 to MCA6006, have been placed in the same position as in deposition 3, but in the tenth bentonite ring, attached to the upper lid of the canister. Figure 3 shows the position of the sensors in this deposition hole.

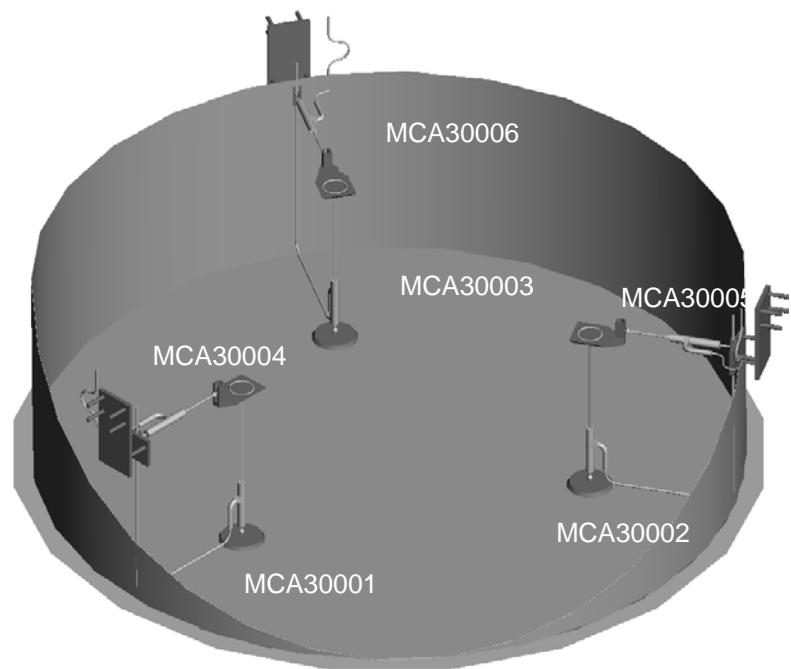

Figure 2. General view of sensors in deposition hole 3

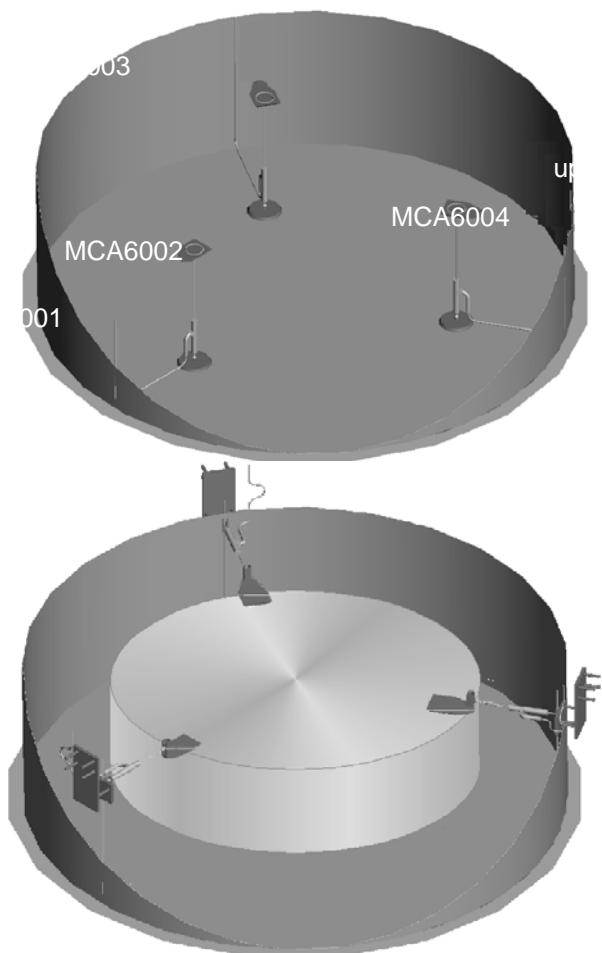

Figure 3. General view of vertical (left) and horizontal (right) sensors in deposition hole 6

2 General comments

This is the fifth “Prototype Repository in Operation” report issued for SKB within the contract No. 10826, and the second semestral one.

Monitoring is carried out since 010623 in deposition hole 3 and since 030429 in deposition hole 6. Day 0 corresponds to 010917 for deposition hole 3 and to 030508 for deposition hole 6. Negative values correspond to a retraction of the transducer, which means vertical sinking or horizontal approaching to the rock surface, depending on the transducer position.

It can be clearly noticed in both holes the moment when the protection plastic sheet was removed, right before the backfilling of the tunnel. At that point, the sensors started registering displacements due to the bentonite swelling.

According to the measures carried out prior to the buffer installation, the water inflow in deposition hole 6 is two times that of deposition hole 3. This could be somewhat noticed when comparing the results from both holes, as the registered displacements in deposition hole 6 are much bigger in one year than those of deposition hole 3 in three years.

The tunnel drainage was closed on 041101 and re-opened on day 041206. There was a power cut in all the canisters from 041202 to 041215.

In deposition hole 3, the closure and subsequent re-opening of the tunnel drainage seem to have had a high influence. In comparison, the power cut had little effect in general in this hole.

On the contrary, no significant effect from the drainage closure and re-opening can be noticed in deposition hole 6, where the effects from the power cut can be more clearly seen.

Only one sensor out of the 12 installed has failed permanently during the monitoring phase. This is MCA30002, one of the vertical sensors in deposition hole 3, which failed on day 117 (020112). Horizontal sensor MCA6006 in deposition hole 6 had a temporary failure from day 677 (050315) to day 706 (050413), and vertical sensor MCA2006 failed from day 721 (050428) and recovered on day 756 (050602).

A major problem has been detected in the computer of the Data Accquisition System, which requires an in situ repair action, so no data could be registered after 050925. The repair action will be carried out in the early 2006.

The results obtained in both deposition holes are described hereafter. Monitoring screens correspond to data of 050925.

3 Deposition hole 3

3.1 Vertical sensors

Two vertical sensors are still in operation in this deposition hole. After an initial small rise of about 0.5 mm, the sensors showed a fast canister sinking that reached about 2 mm below the initial level, when, most likely due to the re-equilibration of pressures below and above the canister, the decrease ceased and the canister started to rise again.

Lately, the rising rate slowed down, although the values of the two vertical sensors were almost on the initial level (less than one millimetre below), and with a small difference between them. This could indicate that no significant canister tilting has occurred, although the third value for defining the plane of the canister base is unavailable.

From day 1163 (041123), a fast sink of the canister could be noticed, in both vertical sensors at the same time. This could be due to the increase of pressure on top of the canister caused by the closure of the tunnel drainage, which was done 23 days before, on day 1141 (041101). The canister sank 3 mm in two weeks, until day 1176 (041206) when the drainage was opened again. On that point the canister experimented a fast rise, of one mm in one day. Afterwards it kept rising at a slow rate, and seem to be stabilising at lower values than those reached before the fast sink..

3.2 Horizontal sensors

At the start of the monitoring phase, two of the horizontal sensors registered an initial small retraction, while the third one registered a similar elongation, all in the order of half of millimetre. This could indicate a horizontal displacement of the canister.

Afterwards, the two sensors showing retraction changed to elongations of about 0.5 mm and 1.5 mm. One of the changes was very fast. No changes were registered in the third sensor, so it is not clear that this is due to a horizontal displacement of the canister. A possible explanation for this behaviour is that it is due to the vertical movement of the canister, although in principle the anchoring points of the horizontal sensors were conceived not to be affected by vertical displacements of the canister.

No changes were registered afterwards until day 1167 (041127), when one of the horizontal sensors showed a fast elongation, followed by a retraction. This behaviour could reflect again the vertical displacement of the canister detected in the same dates, given that the shape of the plot matched exactly the vertical movement and that the other two horizontal sensors did not show any displacement.

4 Deposition hole 6

4.1 Vertical sensors

The vertical sensors maintain their trends from the start of the monitoring phase, showing a constant rise of the canister. Although one of the sensors started increasing later than the other two, all the three are now in similar values, what indicates that no tilting of the canister is taking place. The rising rate has slowed down in the last months, stabilising in a canister rise of about 10 mm.

A small effect from the power cut could be noticed in the three sensors, while no effect from the drainage closure and re-opening could be detected.

4.2 Horizontal sensors

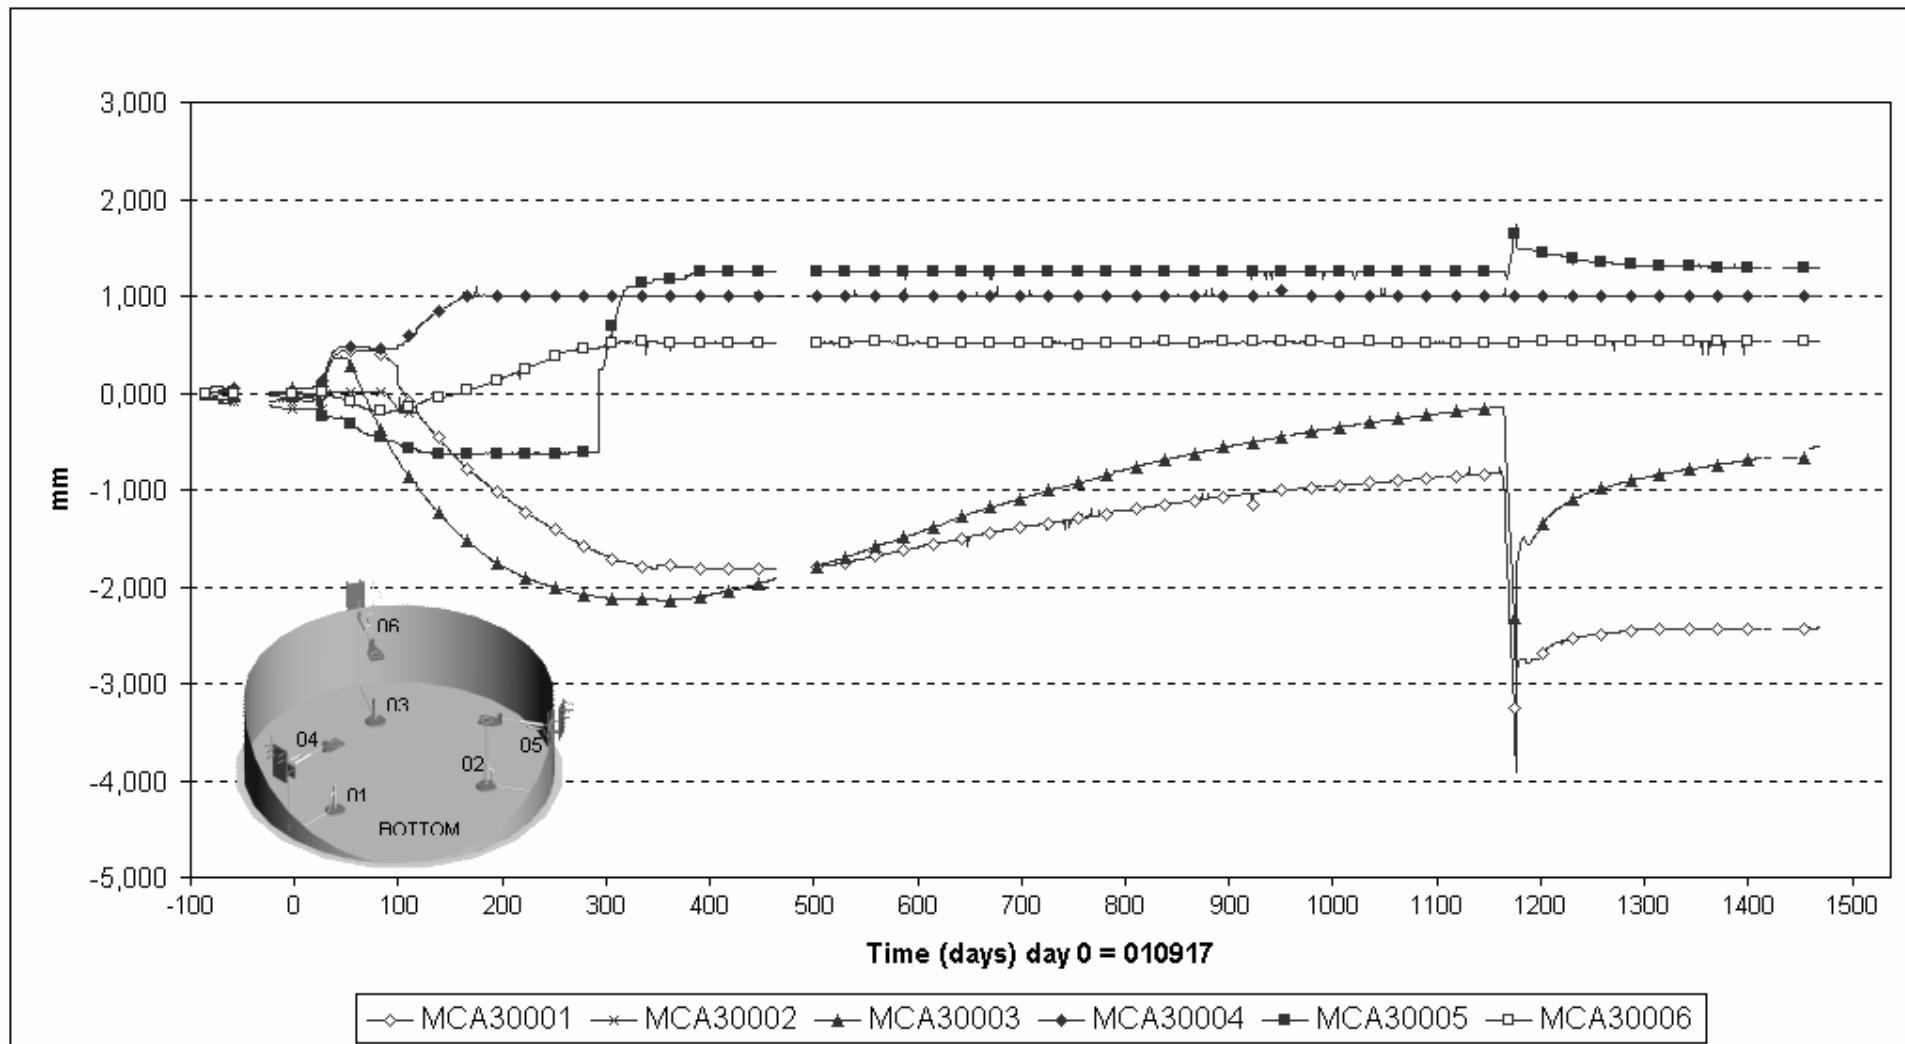

The horizontal sensors showed some fast initial movement at first, with elongation of two sensors and retraction of the third one, what could indicate a canister movement towards this one in the order of 1 mm. Afterwards, one of the elongated sensors, MCA6005, started increasing at a rate similar to the vertical sensors, reaching about 8 mm and still increasing slowly. The other two sensors remained more or less constant.

Given the position of the sensors, a horizontal movement of the canister should result in a similar variation of the three sensors in absolute value, so as for deposition hole 3, it is more likely that the mentioned fast elongation of such sensor was due to the vertical movement of the canister.

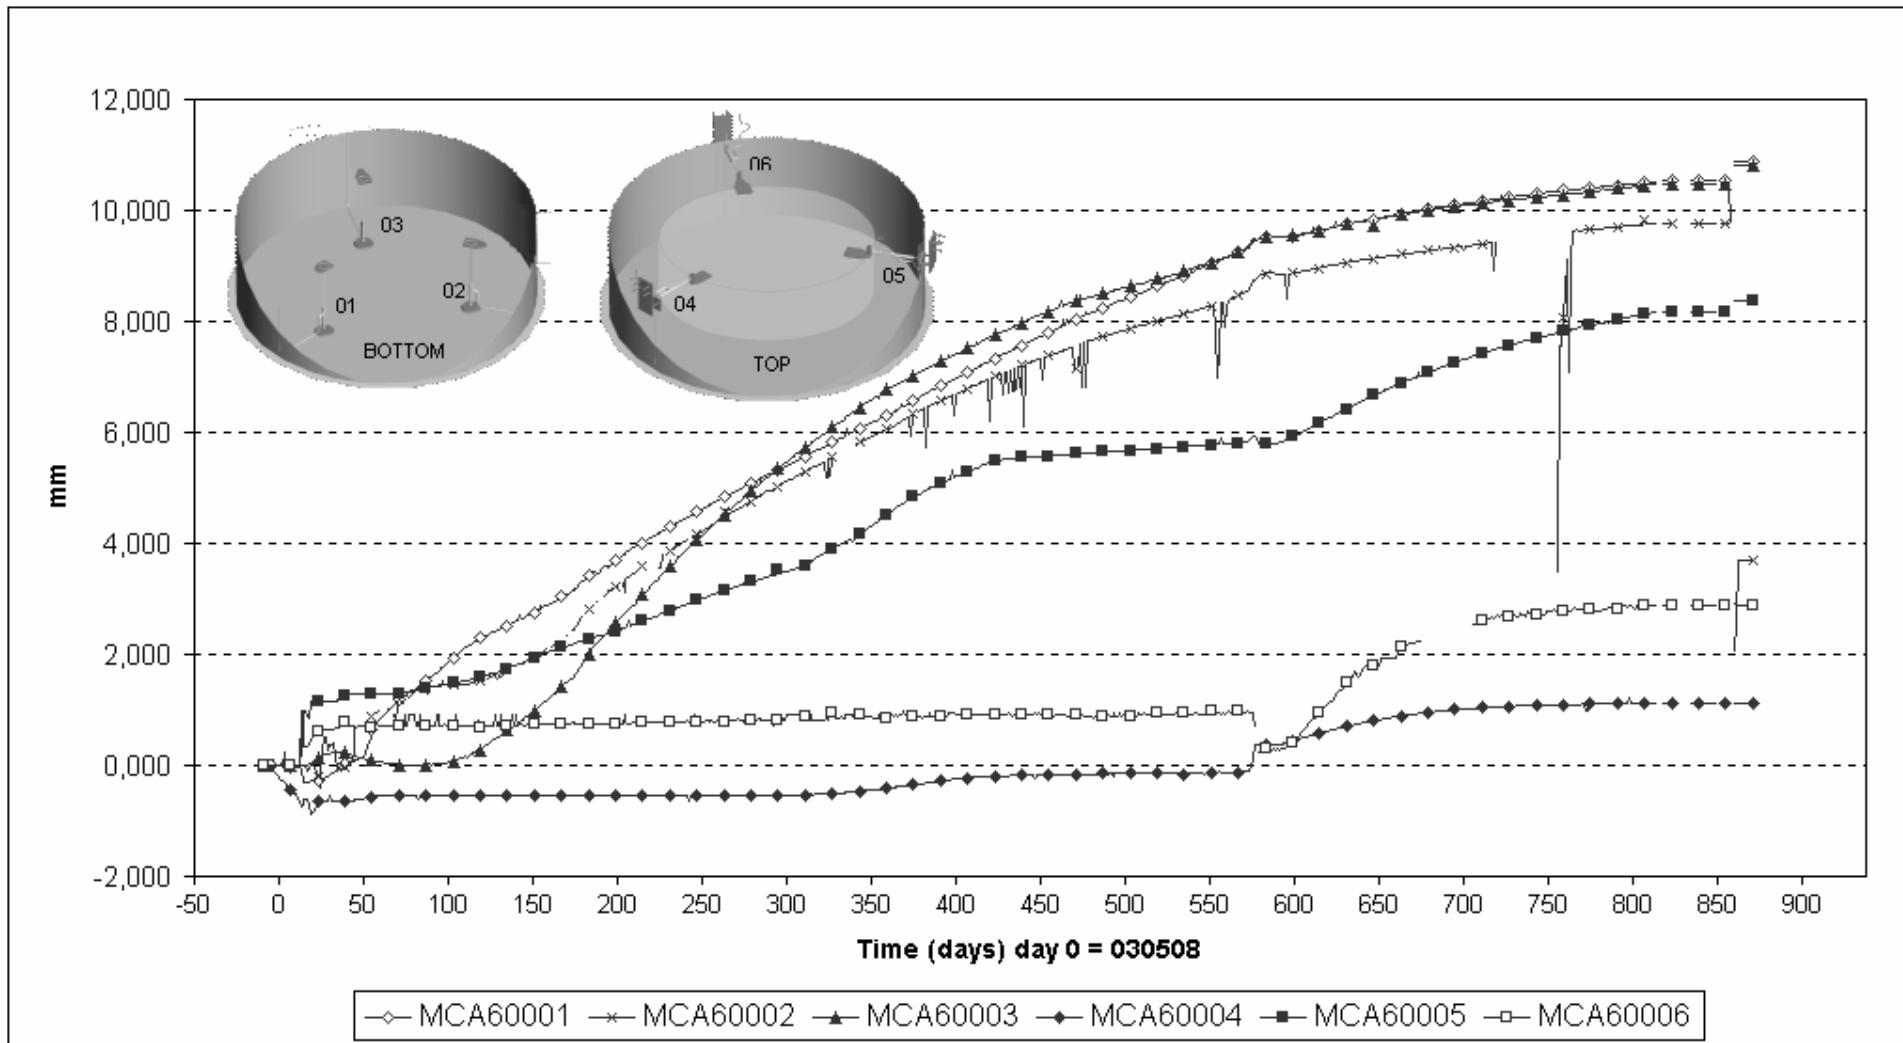

As for the vertical sensors, the effect of the power cut could be noticed, but more clearly in this case. A horizontal movement seemed to occur during those dates, as one sensor showed elongation and the other two showed retraction. No influence of the drainage closure could be noticed.

After that, from about day 600 (041228) all the three sensors showed an elongation of between 1 mm and 2 mm. Again this is likely due to the vertical rise of the canister.

1 Introduction

Within the frame of research activities in the prototype repository at Äspö GRS employs measurements of electrical resistivity to monitor water uptake in the drift backfill, the borehole buffer, and desaturation effects around one of the deposition boreholes.

The electrical resistivities in the buffer, the backfill, and around the boreholes are determined by use of multi-electrode arrays. The arrays consist of electrode chains. The resistivity distribution in the areas between the chains is determined by means of tomographic dipole-dipole measurements. The recording unit for these arrays is controlled remotely from Braunschweig / Germany via a telephone connection, which allows daily measurements of the in-situ resistivity distribution. From the measured apparent resistivity values the "true" resistivity distributions in the different parts are computed applying the latest inversion software.

In the geoelectric measurements advantage is taken of the dependence of the electrical resistivity in materials on the water (solution) content. In order to interpret the resistivity values in terms of water content the data are to be compared with laboratory calibration results which are available for the different materials.

In the following, quarterly calculated inversion data for the different arrays are provided in the form of tomograms. Additional data for smaller time periods can be made available on demand.

2.3 Actual Interpretation

The initial resistivity value of the backfill in October 2001 is about 10 to 14 Ωm corresponding to a water content of 13 to 14%. In the following month the resistivity reduces to about 7 to 10 Ωm which corresponds to a water content of about 14 to 16%. However, this reduction in resistivity is most likely generated by the wet (light blue) areas close to the electrode chains. These wet areas are the consequence of moistened backfill used during installation of the electrodes for better covering of the electrode chains. From then on, the resistivity decreases continuously, starting near the drift walls and progressing into the drift centre. Since November 2004, a very homogeneous resistivity distribution has been reached; with a value around 3 Ωm corresponding to a water content of 21 - 22 %. Resistivity is still slowly decreasing, but the backfill is not far from full saturation.

Besides this overall trend, minor changes in the tomograms from month to month are visible near the edges of the gallery, especially a light blue area on the right side of the tomograms is more or less pronounced. These are no real anomalies, but are caused by the fact that inaccuracies in the measurements can lead to the accumulation of "ghost" anomalies in areas of lower sensitivity. The areas of lower sensitivity are typically the edges of the model. In case of the blue area on the right side of the tomograms, the sensitivity is more reduced because one of the electrodes (marked with an "x" in the tomograms) is not active, as its cable broke after installation during backfilling.

The resistivity is also slightly decreased by the temperature increase in the backfill. The temperature increase can result in a resistivity reduction by not more than 1 Ωm .

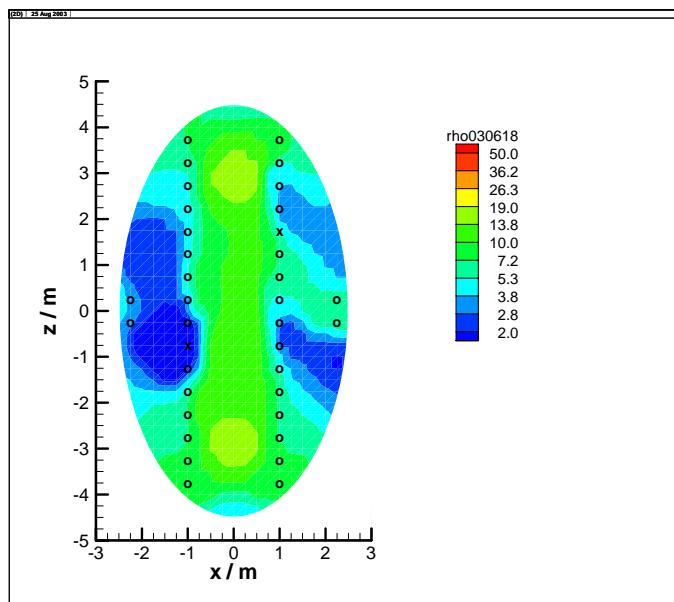

On May 2, 2003, the upper right electrode (also marked with an "x" in the tomogram from May 31, 2003) was lost. The reason is probably a cable failure. It is not clear whether this is already a corrosion effect.

3 Backfill Section 2

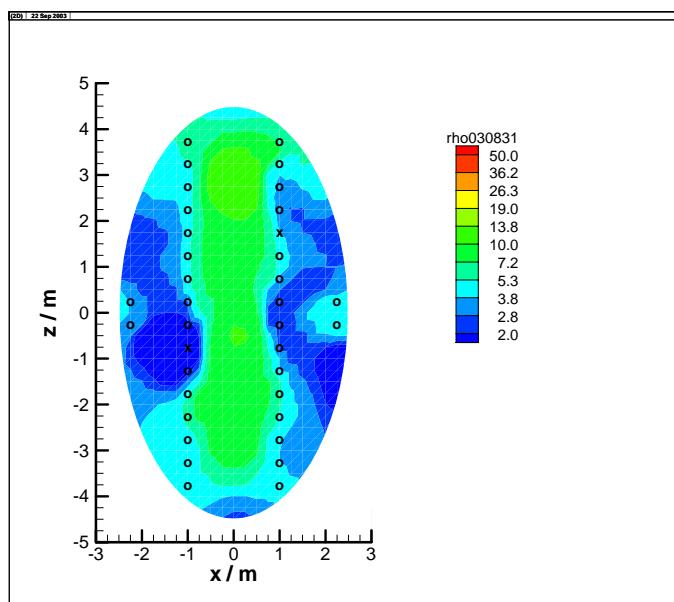

3.1 Layout of electrode array in the backfill of section 2

The array layout in the backfill of section 2 is identical to that located in section 1, except for the fact that the array has been placed above deposition borehole #6 instead of #3.

3.3 Actual Interpretation

The first measurement performed on June 18, 2003 in section 2 shows a much lower resistivity than the early measurements in section 1. Obviously, the backfill had a considerably higher water content already during installation. This observation was also made during instrumentation. Resistivity is decreasing further from the drift walls. Close to the walls it ranges below $3 \Omega\text{m}$; the backfill is therefore not far from full saturation. In the centre resistivity has decreased to values around $3 \Omega\text{m}$ corresponding to a water content of 21 to 22%.

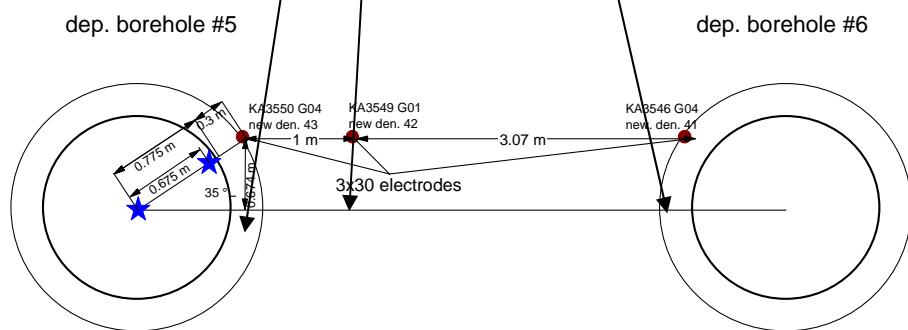

4 Rock Section 2

4.1 Layout of electrode array in the rock between deposition boreholes 5 and 6

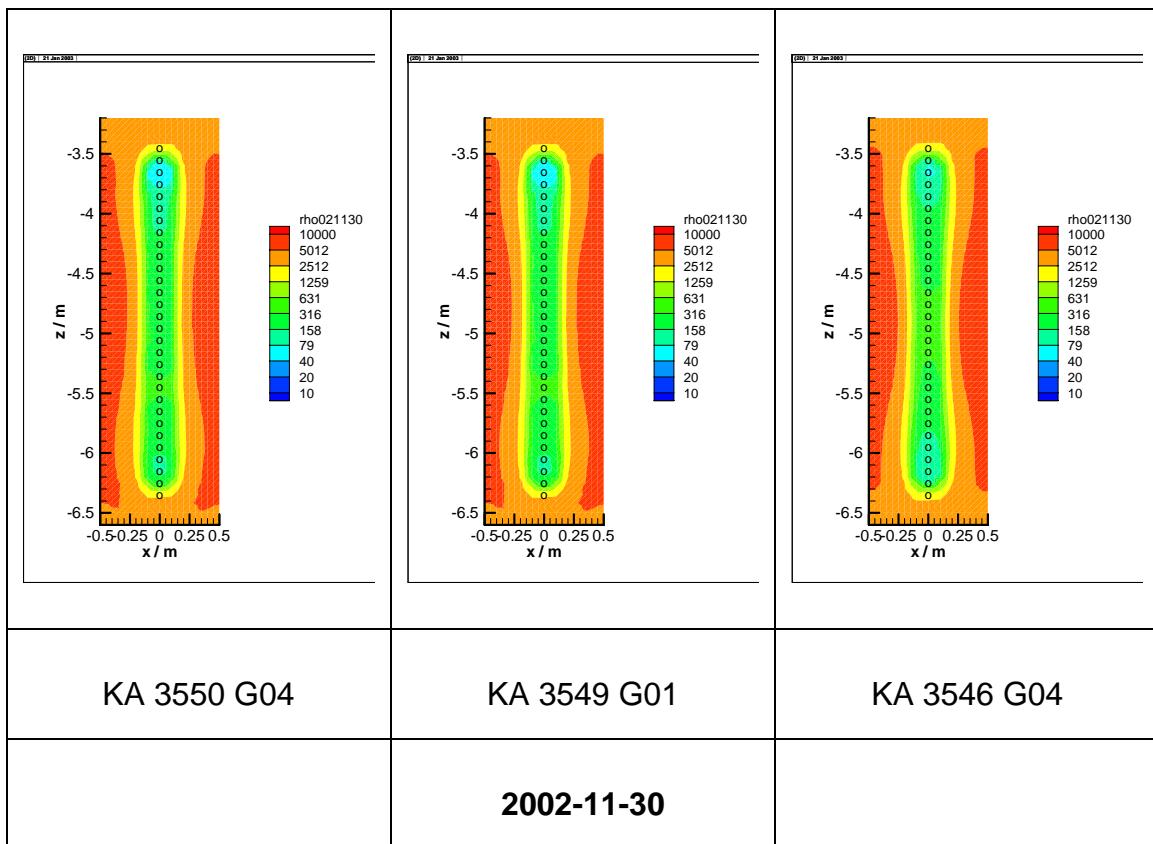

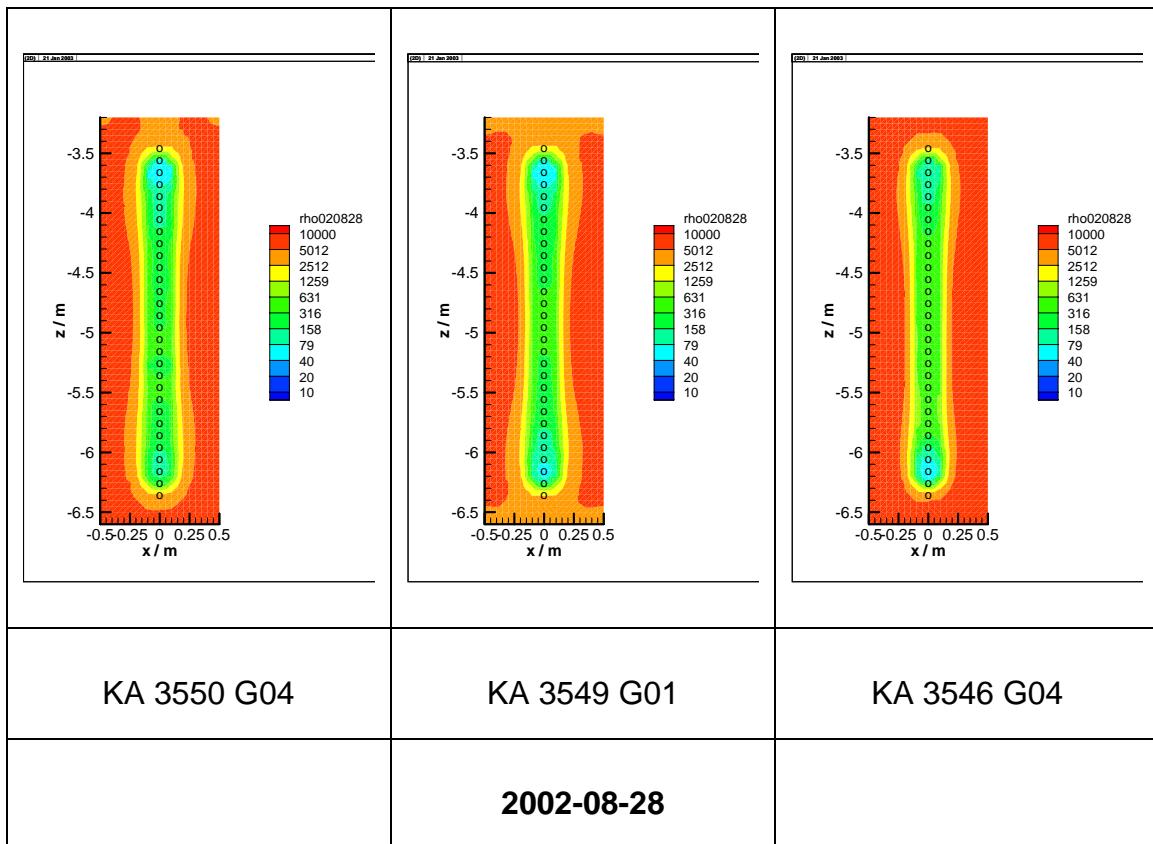

A) Vertical cross section

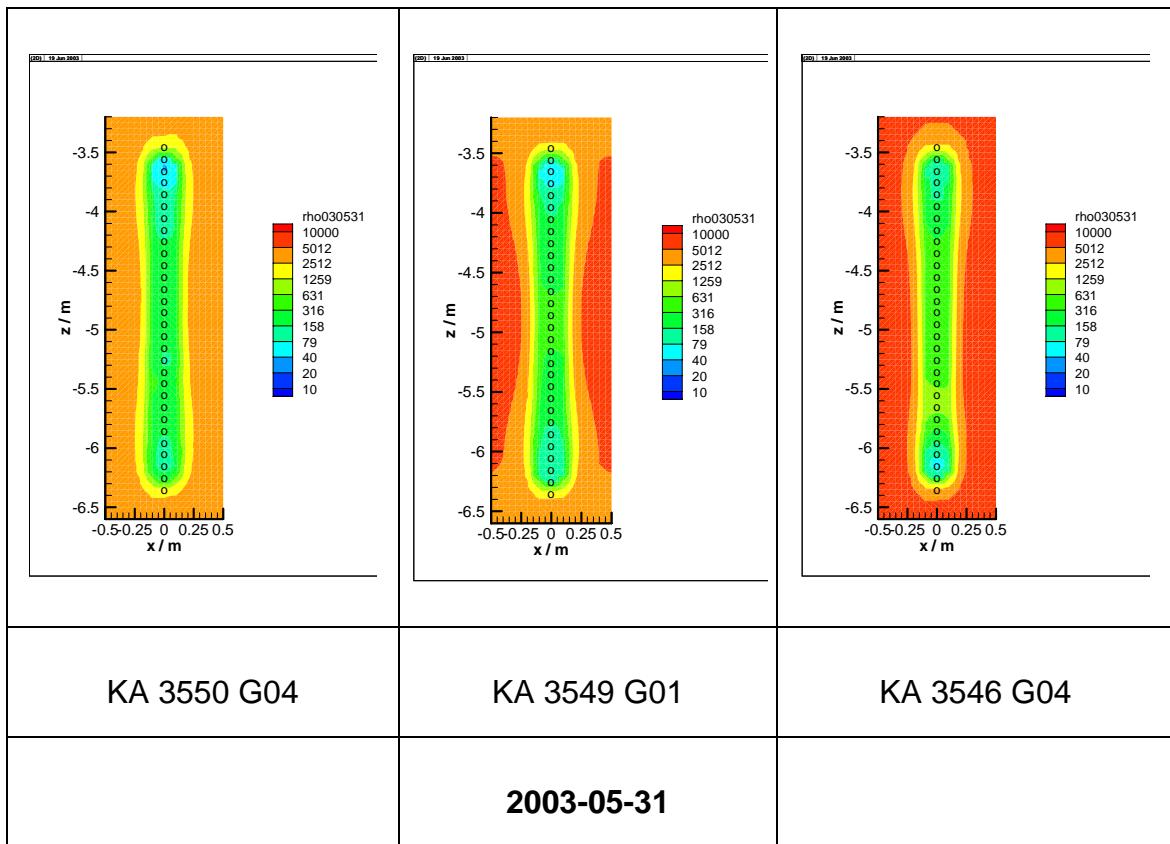

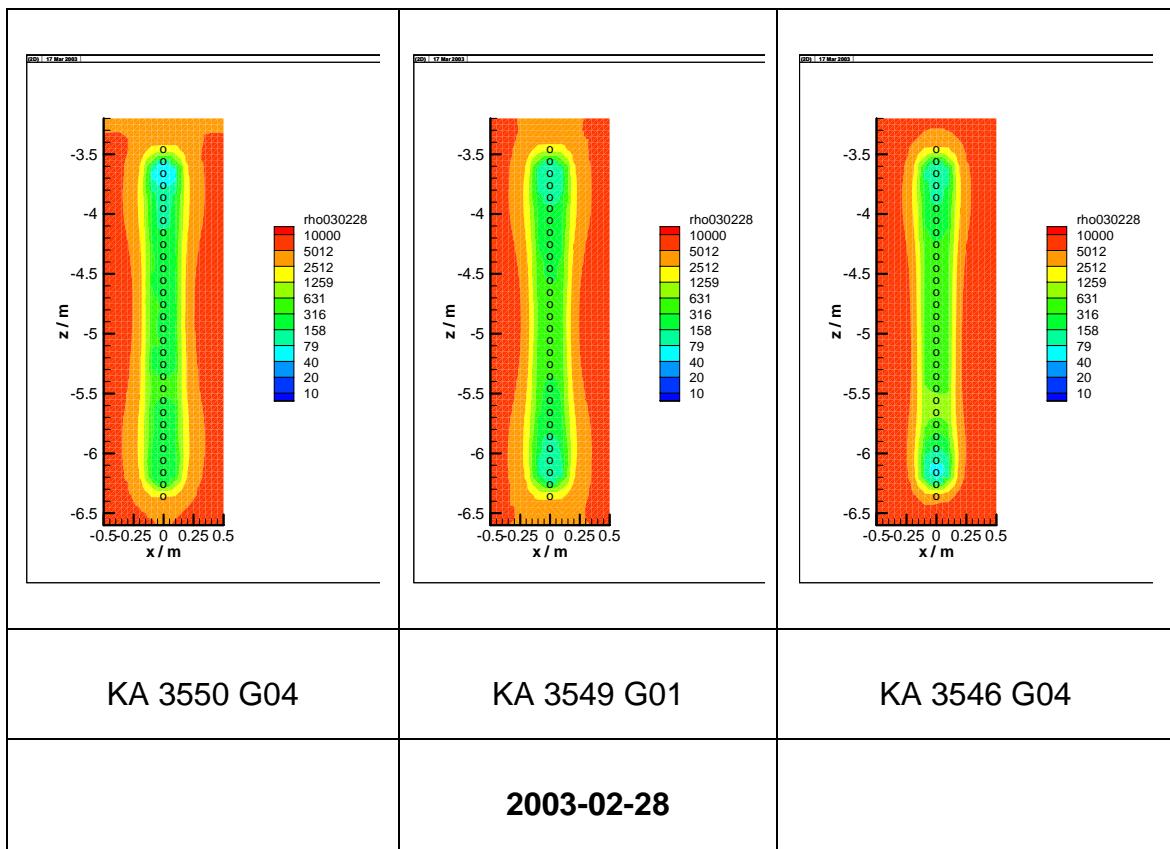

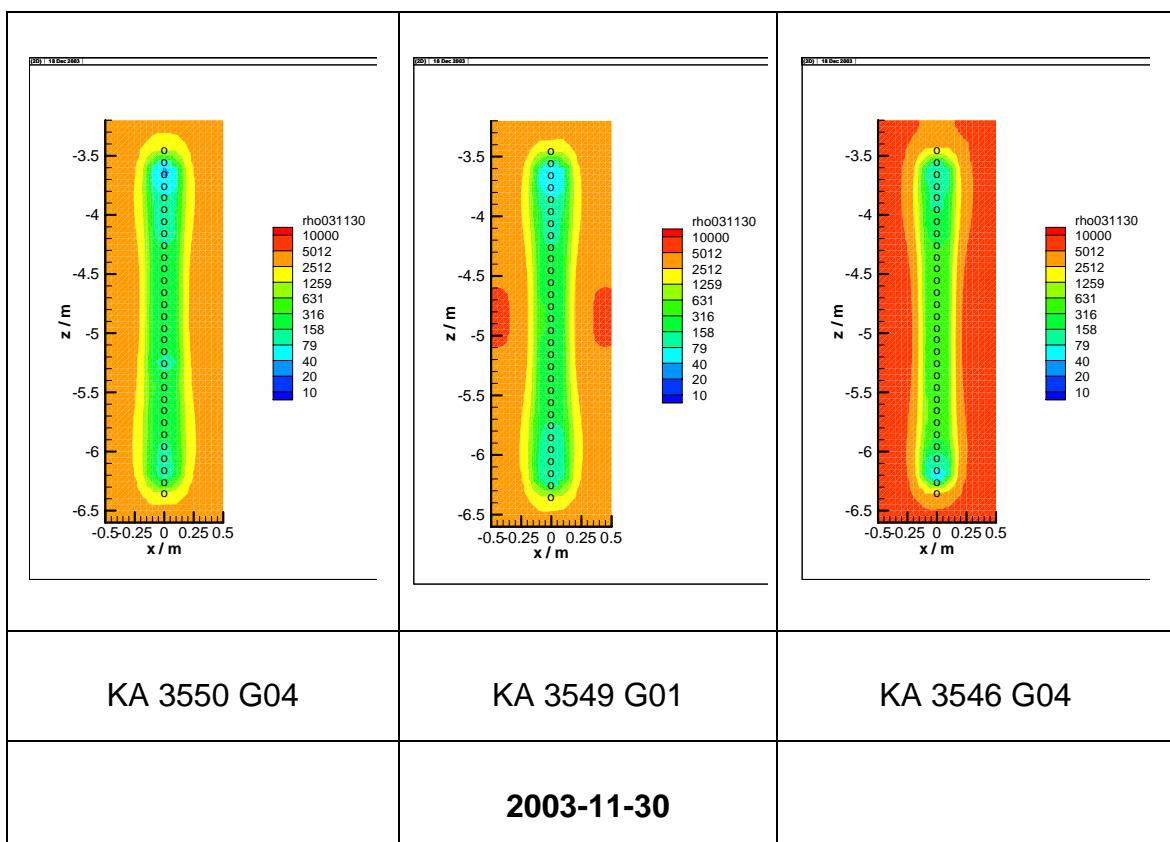

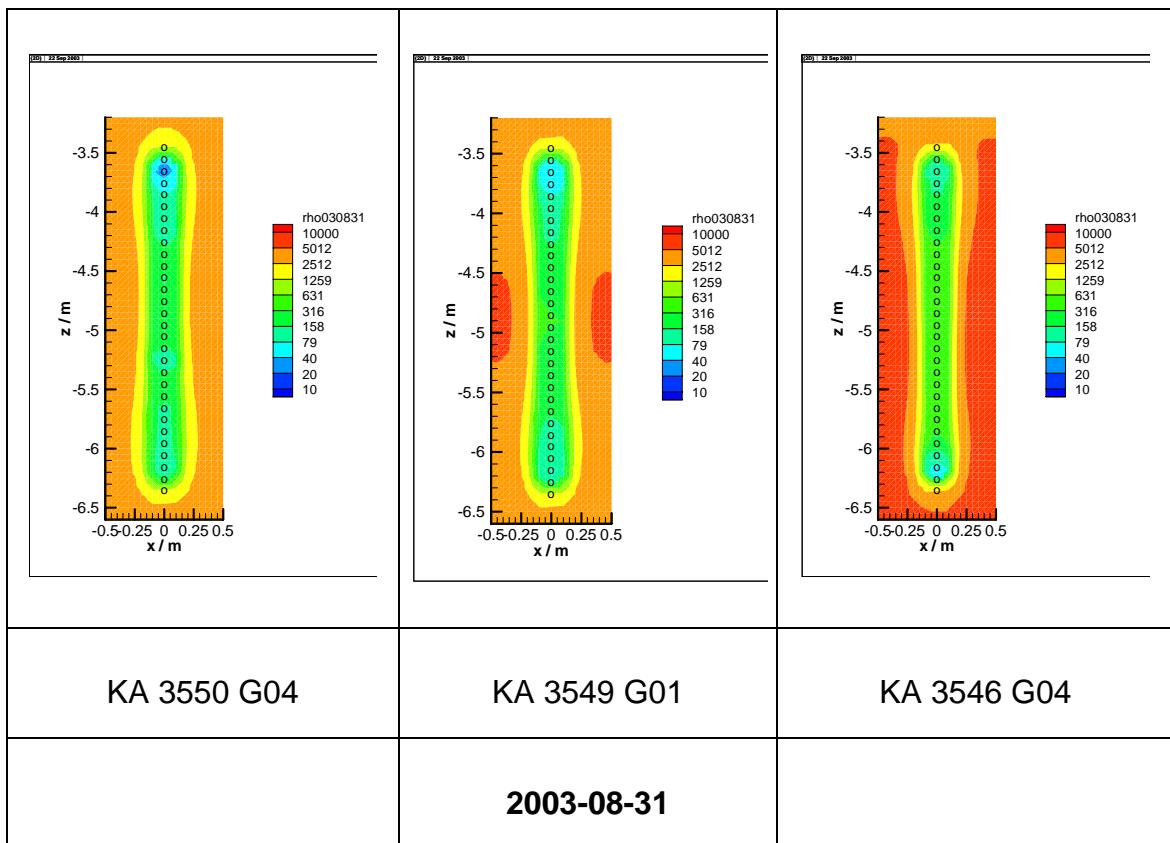

B) Plan view

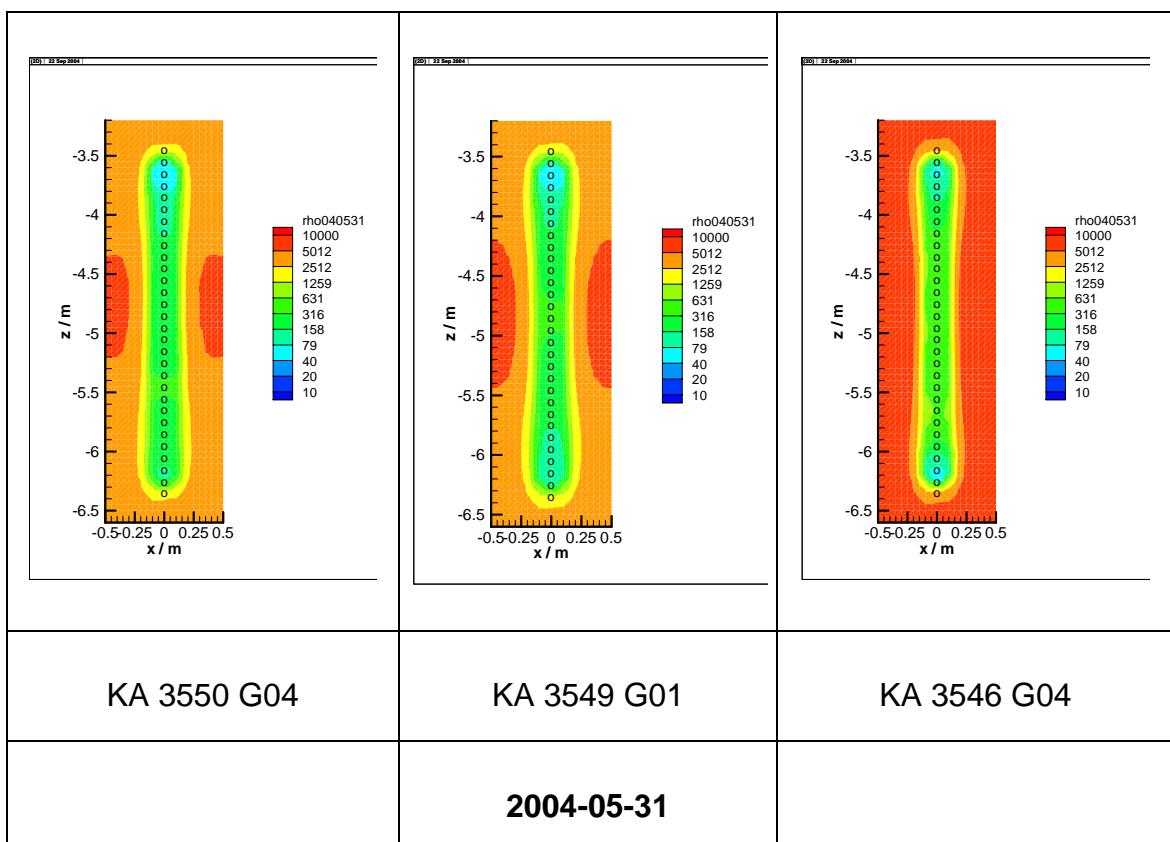

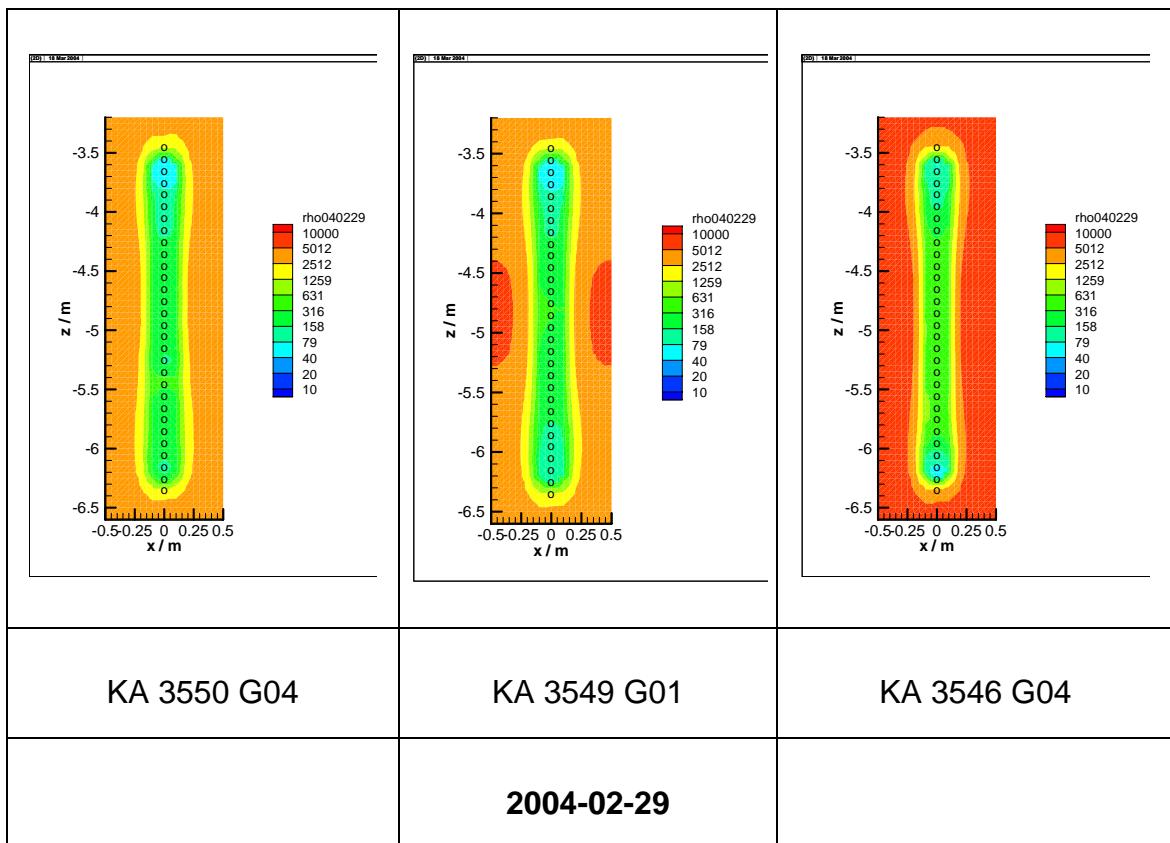

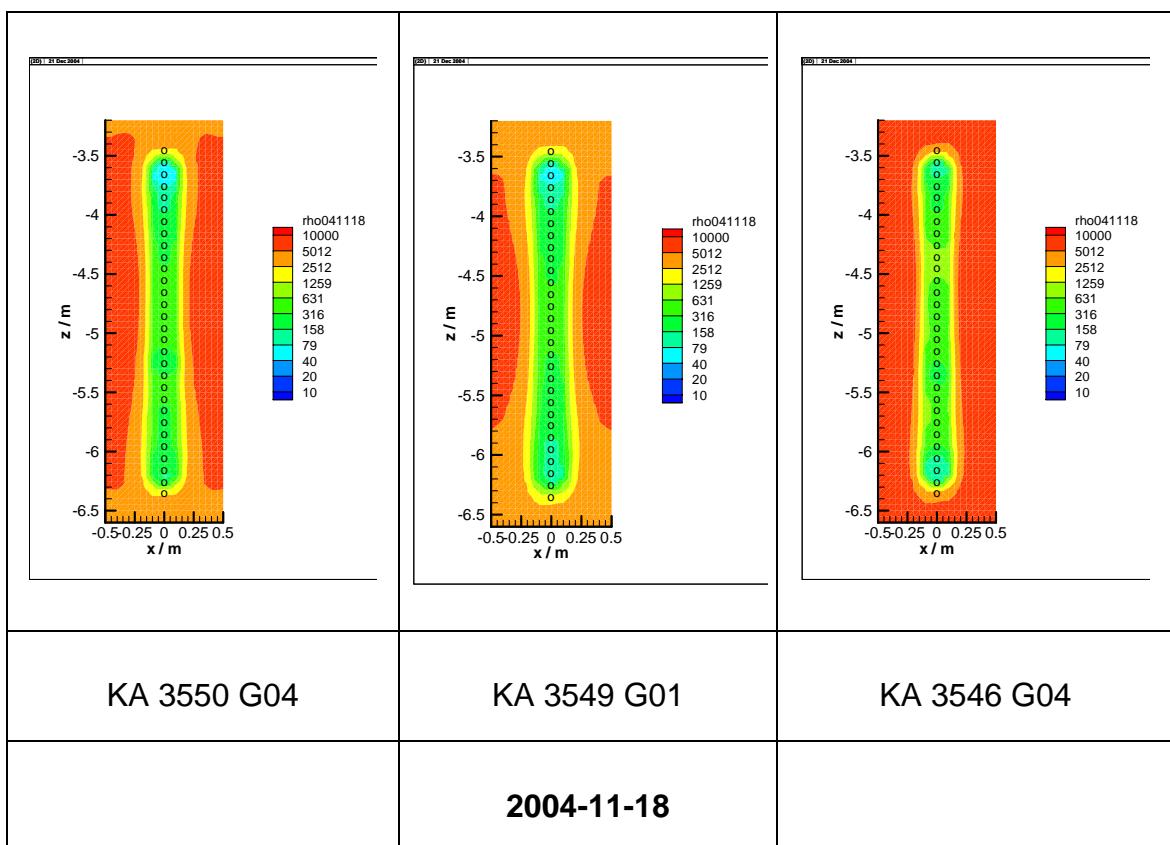

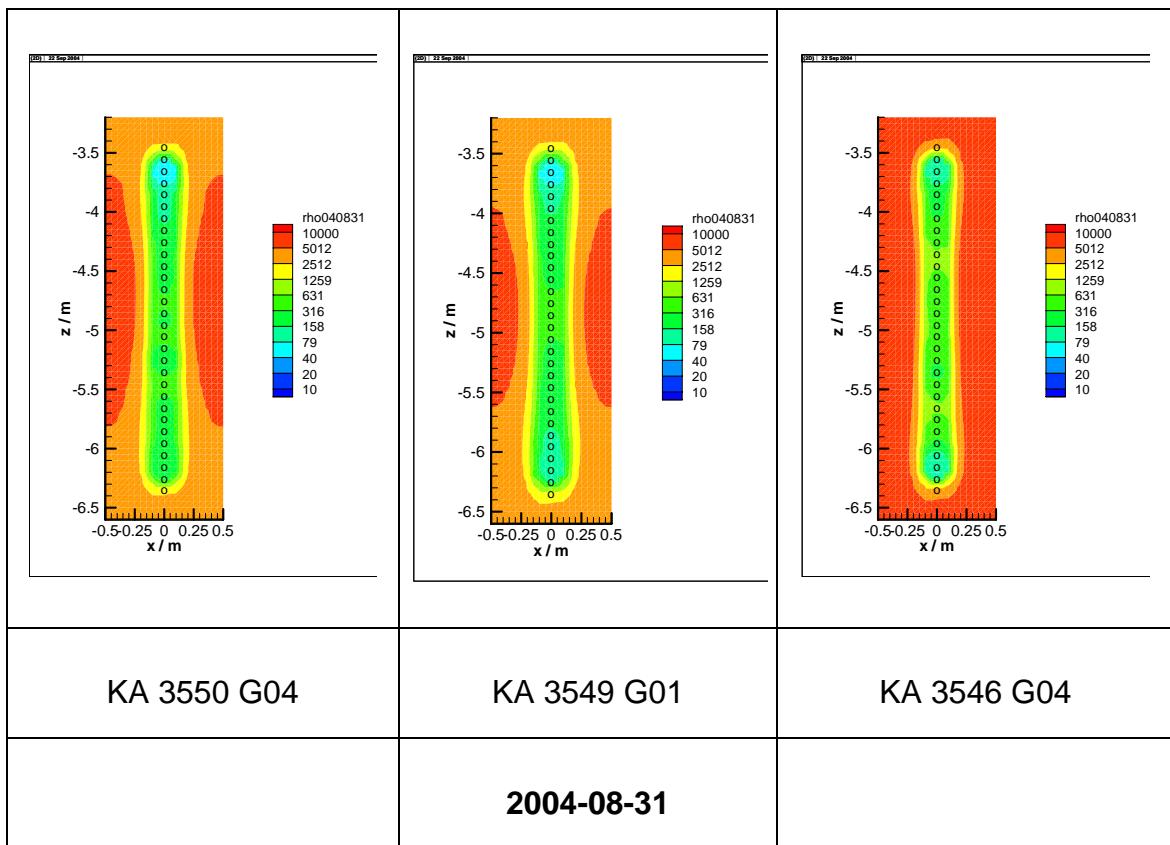

4.2 Tomograms of electrode arrays in the rock

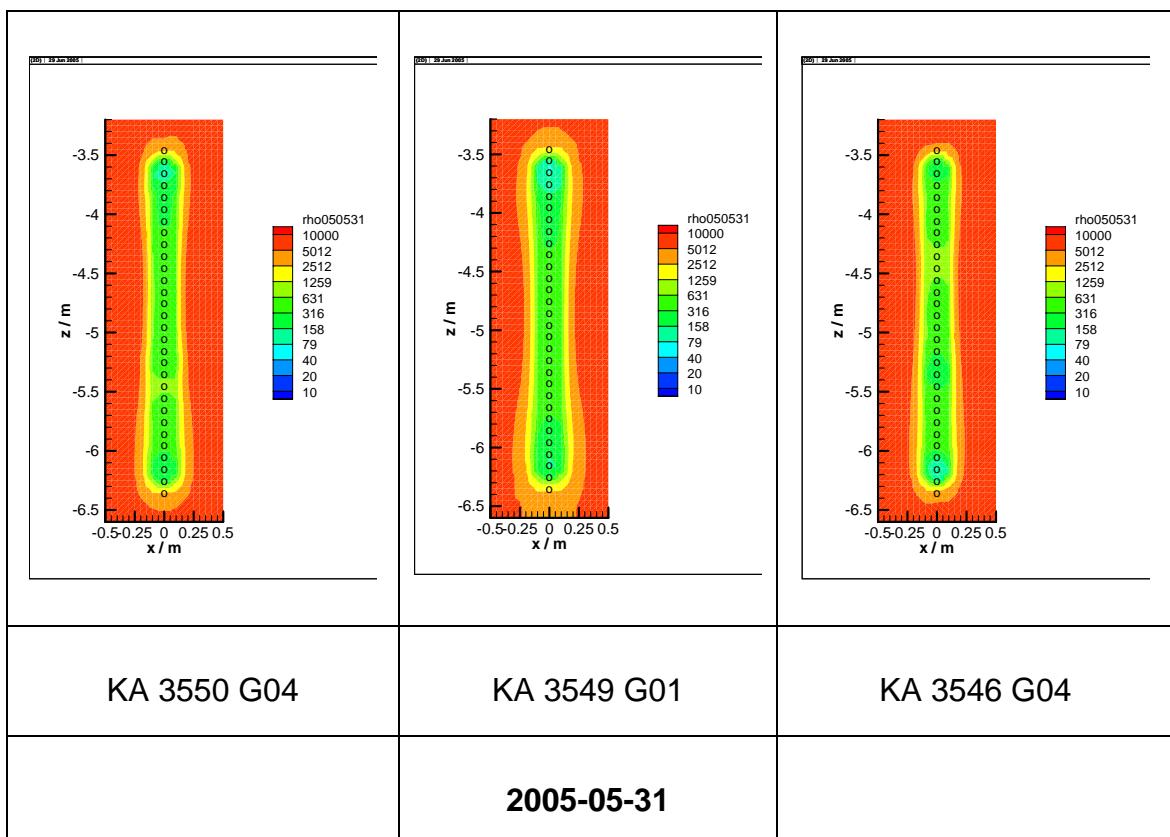

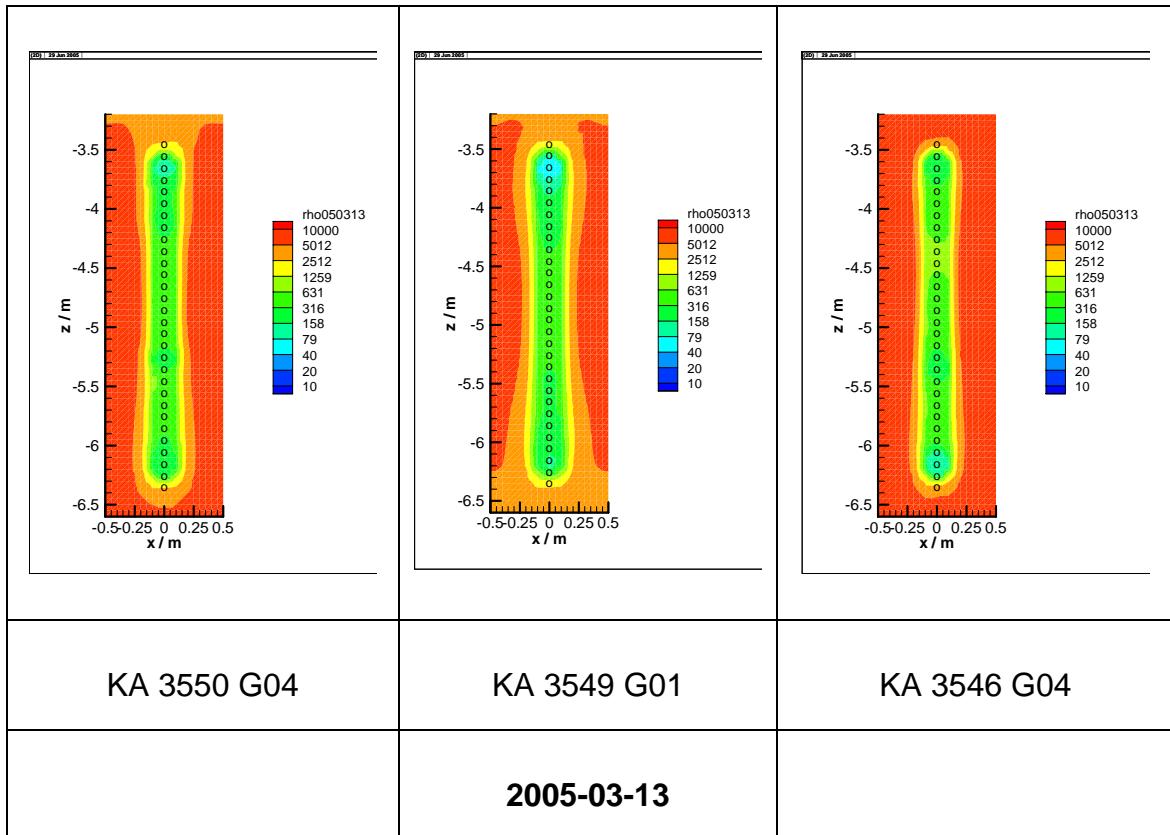

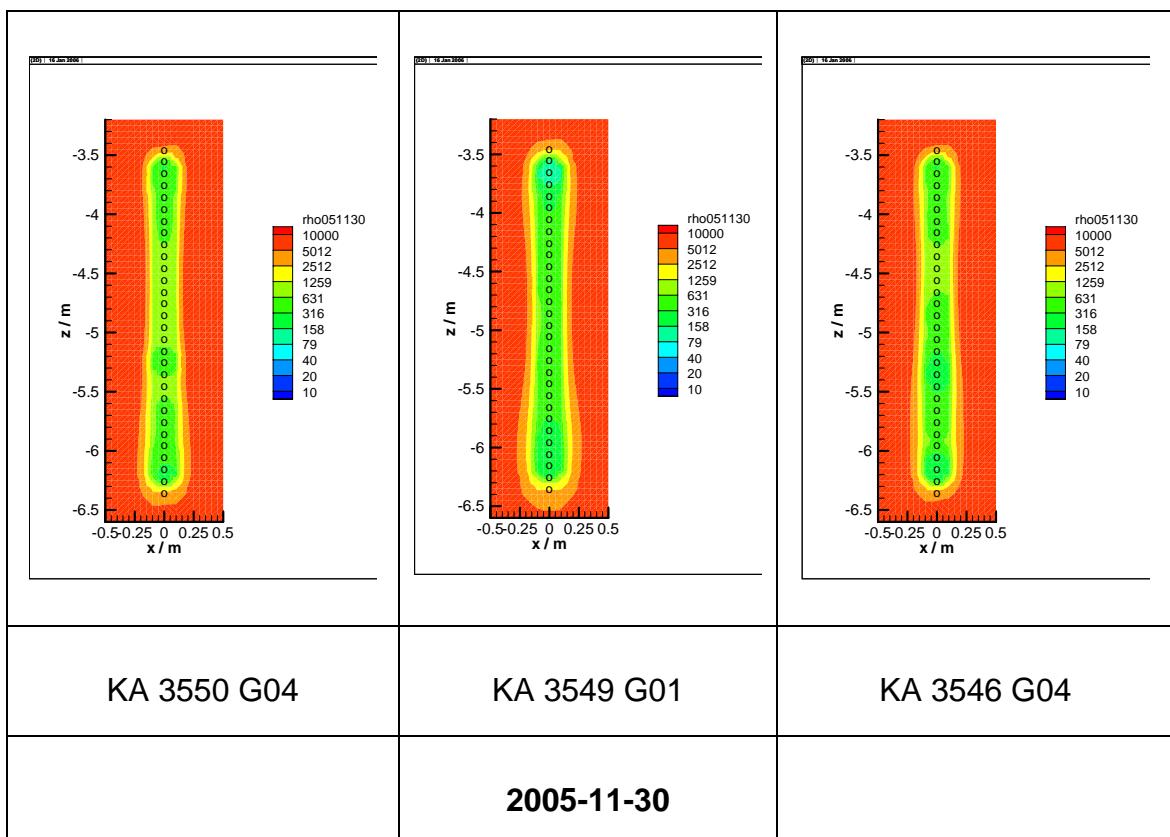

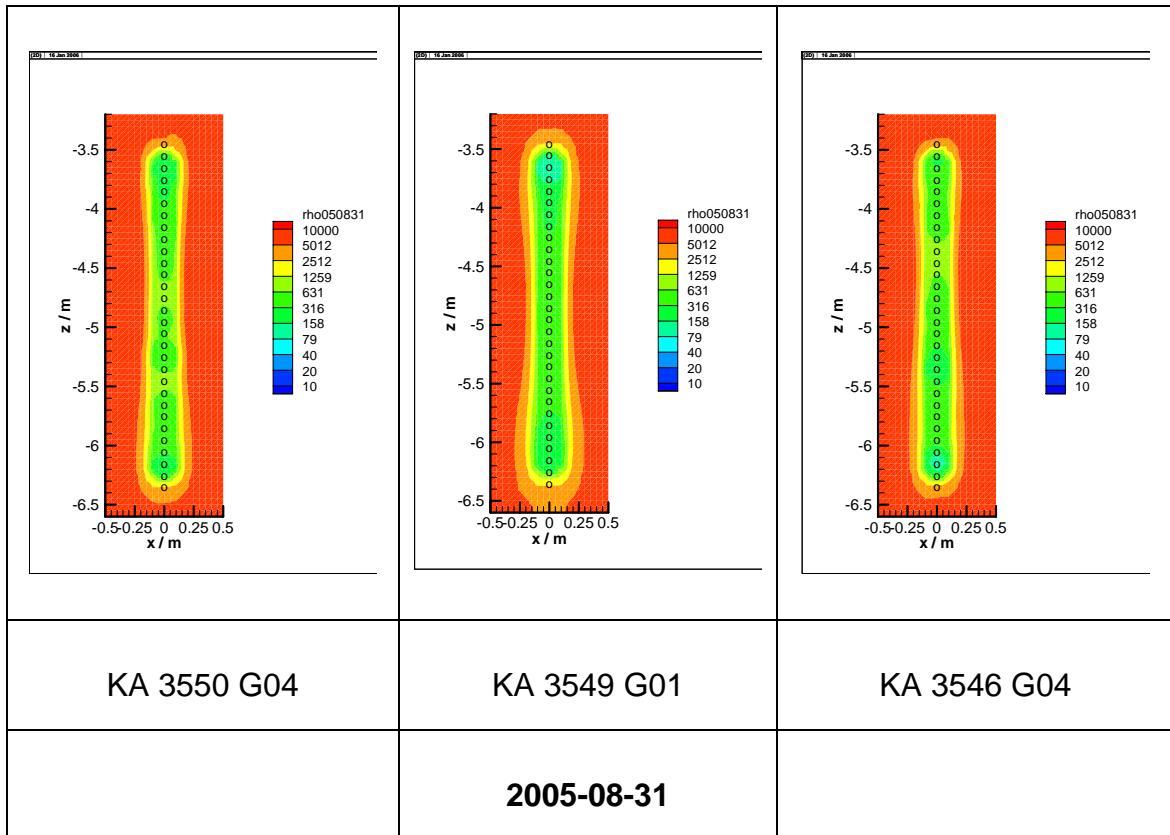

4.3 Actual Interpretation

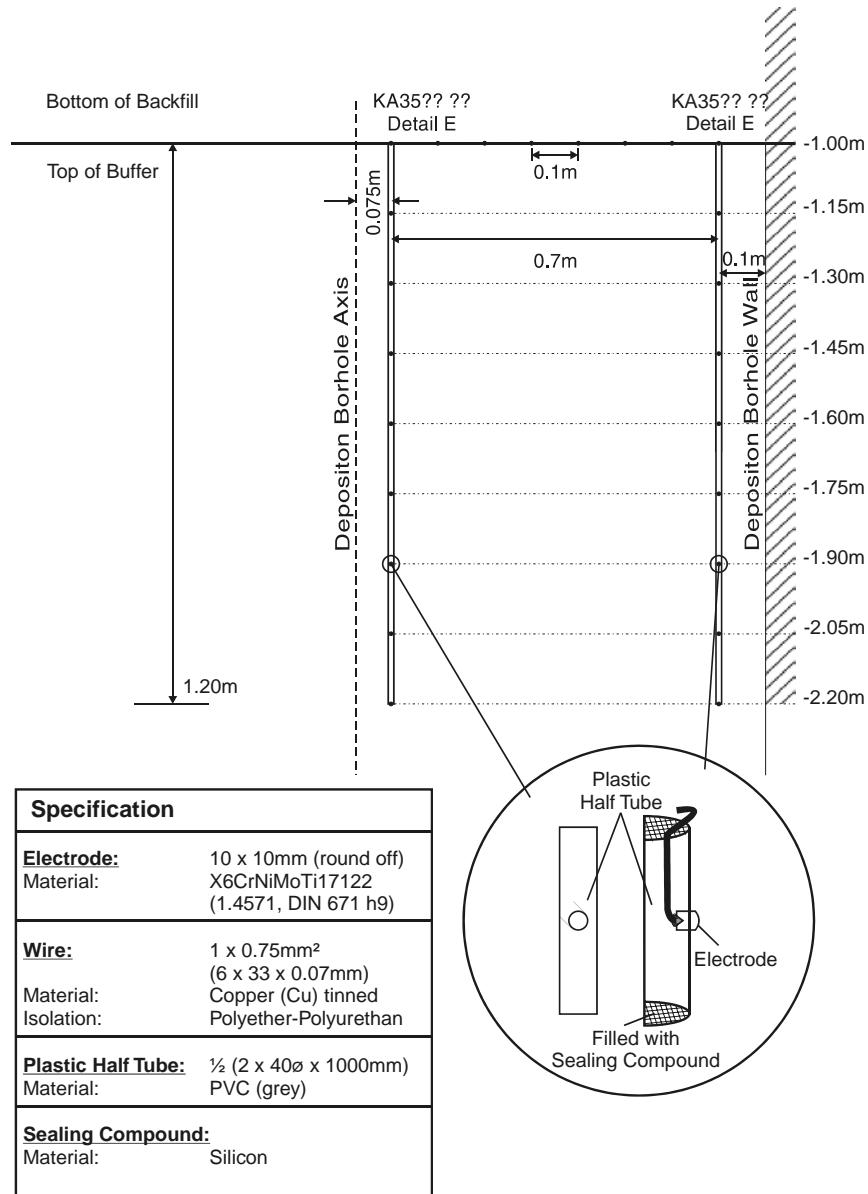

The resistivity distributions along the three electrode chains installed in the rock are quite similar to each other and show no significant variation in time until April 2003. Close to the electrodes, the resistivity ranges around 200 Ωm . This value characterizes the water-saturated concrete used for backfilling the electrode boreholes. Further away from the boreholes, the resistivity rises to values of 2000 to 7000 Ωm which is characteristic for water-saturated granite.

From April 2003 on, there is a slight decrease in resistivity in the rock near deposition hole #5. This coincides with installation of the buffer which also stopped the pumping of water from the open deposition hole. Apparently, this had caused a slight desaturation of the rock which recovered. From February 2004, resistivity seems to slightly increase again. Near the deposition hole #6, no such effect was detected.

5 Buffer in Borehole 5 in Section 2

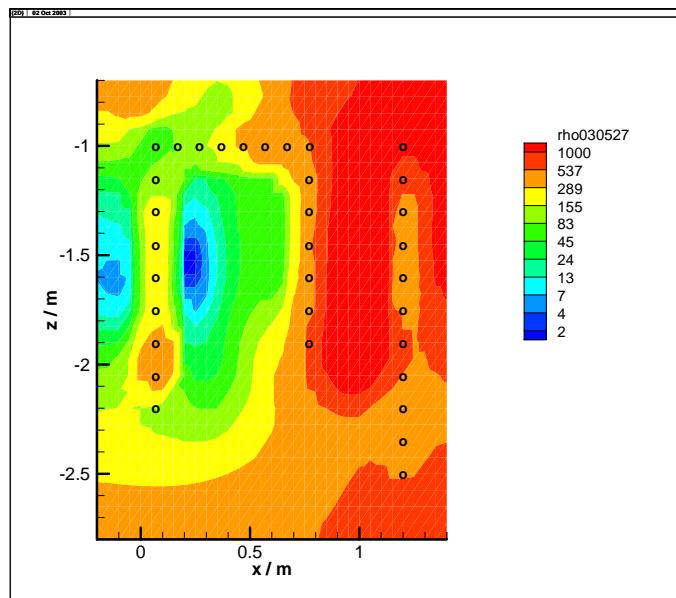

5.1 Layout of electrode array in the buffer of deposition boreholes 5

The array is made up of the electrodes located in the buffer at the top of deposition hole #5 (see figure) and of the electrodes in the upper part of borehole KA 3550 G04 in the rock (see figure in section 4.1).

5.3 Actual Interpretation

The tomogram of May 2003 (first measurement) shows the high resistivity (above $1000 \Omega\text{m}$) of the rock on the right side and the low resistivity of the buffer (below $80 \Omega\text{m}$). The picture is somewhat distorted by the fact that along the electrode chains the resistivity is increased compared to the undisturbed buffer. The increased resistivity along the electrode chains can be attributed to the refilling of the electrode boreholes with bentonite powder produced during borehole drilling. It was, however, expected that the difference will diminish with time, especially if the buffer takes up water. The tomograms of the following months show a progressing decrease of resistivity in the buffer. While the overall behaviour is rather clear, it is difficult to interpret buffer resistivity in terms of water content. In nearly all the buffer monitored by the array the resistivity has decreased to values below $24 \Omega\text{m}$ by November 2004 and below $13 \Omega\text{m}$ by end of May 2005. The tomogram of November 2005 shows two high resistivity anomalies in the buffer. These are not real, but result from the fact that two electrodes have been lost between September and November, 2005. The accuracy of the results is reduced by the loss of electrodes. Currently, the measurement control file is adapted in order to maximize the number of reliable measurements and leave out the lost electrodes.

2006-02-14

BergByggKonsult AB Ankdammsgatan 20 171 43, Solna, Sweden

Tel. 08-7595050 Fax. 08-7595065

1 Extent

BBK AB and NCC Teknik have, on commission of SKB, ÄSPÖ Hard Rock Laboratory, performed rock mechanical measurements in the Prototype tunnel at Äspö. The measurement program comprises registration of the stress and strain response around the two deposition holes during drilling and heating of the rock mass.

In the first phase, the response of the rock mass was monitored during the drilling of the two canister holes. The second phase, which is the subject of this report, includes the response registered during a heating phase. The heating experiment started on 2003-05-08 and will continue for about five years.

The goal of the instrumentation is to monitor the stress, strain and deformation changes due to heating of the rock mass surrounding the deposition holes. Instrumentation has been installed to monitor the relative changes in intact rock as well as across fractures.

The commission extends over field measurement and evaluation.

BBK AB is responsible for measuring equipment, the mobilization, field measurement, the computer processing. BBK AB and NCC Teknik are responsible for the interpretation and reporting of the measurements.

This report presents the measurement results during the period of the heating phase from 2005-06-01 to 2005-11-30.

2 Technical background

2.1 Summary of instruments installed

The instrumentation for monitoring rock mechanical response was installed in two stages. The instruments used to monitor the drilling phase of the canister boreholes were installed within vertically drilled boreholes located 0.3m from the periphery of the deposition hole. These instruments are referred to as primary instruments in the following section. Following drilling of the deposition holes, complementary instruments were then installed within boreholes drilled from within the deposition holes.

The following numbers and types of instruments were selected for installation to allow monitoring of stresses and strains within the host rock surrounding the deposition holes.

Table 2.1. Summary of primary instruments

Parameter measured	Instrument type	Total number installed
Compressive stress change in intact rock	Geokon model 4350 biaxial stressmeter	8
Compressive and tensile stress change in intact rock	Geokon model 4360-1 Soft stress cell	8
Vertical movements in intact rock, over single fractures and within fracture zones	Geokon model 4430 deformation meter	17
Vertical strain measurements in intact rock and over single fractures	Geokon model 4200 strain gauge	7

Table 2.2. Summary of complementary instruments

Parameter measured	Instrument type	Total number installed
Horizontal deformation perpendicular to the axis of the deposition hole	Geokon model 4430 displacement transducer	32
Vertical strains beneath the deposition hole	Geokon model 4200 strain gauge	8

The layout of the primary instruments around the deposition holes is shown in Figures 2.1 and 2.2. A total of eight 60mm diameter boreholes (four around each of the two deposition holes) were drilled. The majority of the instruments were installed within these boreholes. These holes are designated as A, C, E and G- 5 and 6. In addition, a total of four 76mm diameter boreholes (two at each deposition hole) were drilled to shallower depths to allow installation of the soft stress cell meters. These larger diameter holes are designated as H and D-5 and 6.

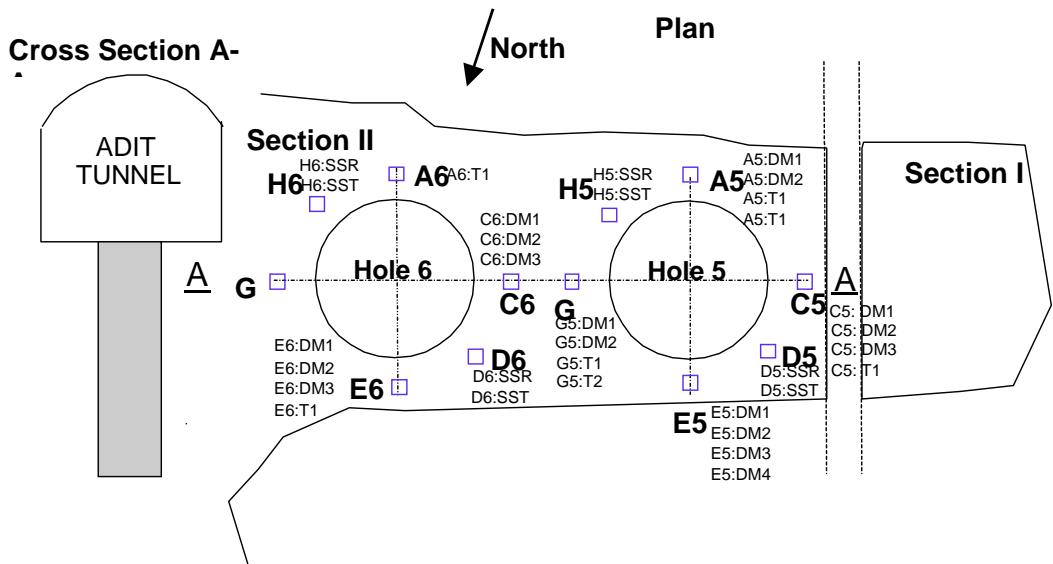

Figure 2.1 Primary instrument locations in plan view

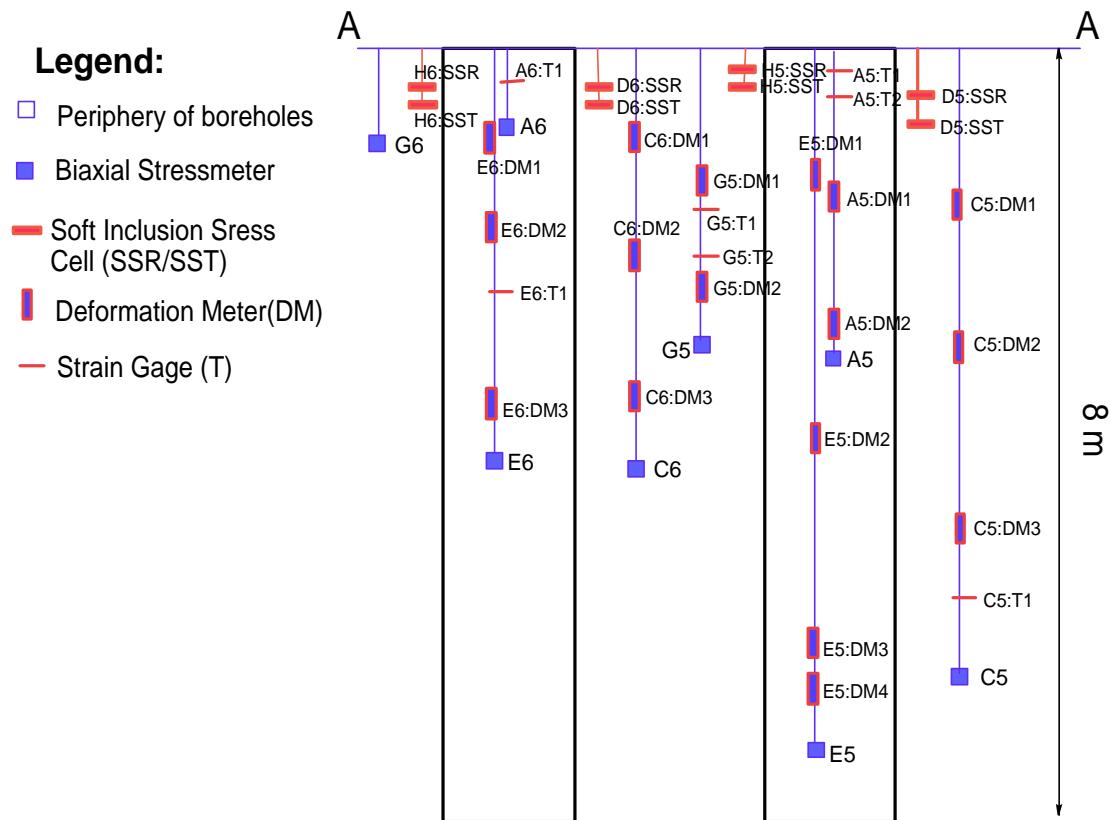

Figure 2.2 Primary instrument locations in elevation view

Installation of the complementary instruments took place following drilling of ten boreholes having about a 75mm diameter from within the two deposition boreholes. The locations of these ten boreholes are shown schematically as well as in plan and elevation in Figures 2.3 to 2.6. The instruments installed within these boreholes consisted of displacement transducers ranging in length from 0.3m to 1.2m, and strain gauges which were 0.15m in length.

Figure 2.6 Elevation view of complementary instruments in Deposition Hole 6

2.2 Stress measurements

2.2.1 Vibrating wire embedment biaxial stressmeters

The Geokon model 4350 vibrating wire biaxial stressmeter was installed for monitoring stress changes. This instrument was designed to measure compressive stress changes in rock, salt, concrete or ice. The instrument consists of a stiff high-strength steel cylinder, which is grouted into a BX (60 mm) size borehole. Stress changes in the host material cause the cylinder to deform, and the deformations in the plane perpendicular to the borehole are measured by means of two sets of three vibrating wire sensors spaced at 60° intervals (measurements are made at two levels within the cylinder). The gauges also include two longitudinal strain sensors and temperature sensors. The deformation of the steel cylinder, and resulting changes in resonate frequency of the vibrating wires, are used to determine both the magnitude and orientation of the change in stress in the host material.

Installation of the stressmeter gage is accomplished by inserting the gage into a grout-filled borehole using a setting tool and self-aligning setting rod. The stress cell is orientated so that the first vibrating wire is orientated tangentially to the canister hole. The second wire is orientated 60° from tangential direction and the third wire is orientated 120° from tangential direction.

2.2.2 Vibrating wire soft inclusion stress cell

The Geokon model 4360 soft inclusion stress cell is designed to measure changes in borehole diameters caused by changes in stress in rock and concrete. In use, an instrumented steel ring is installed in a borehole and pre-stressed in place by forcing platens into contact with the borehole walls. A vibrating wire strain gage measures the deformation of the ring, which is also the deformation of the borehole. Both compressive and tensile measurements can be made. Unlike the biaxial stressmeters that contain sets of 3 vibrating wires, the soft stress cells measure deformation changes in only one direction. For this reason the soft stress cells are installed in pairs to measure stress changes tangential and radial to the deposition holes.

2.3 Deformation gages

Deformations around the deposition holes are measured with deformation gages installed both within the same boreholes used for the biaxial stressmeters, as well as in the horizontal complementary boreholes.

The Geokon model 4430 Deformation gage is designed to measure longitudinal deformations in boreholes. The deformation meter consists of a tube with an anchor at each end. Within the tube a beam of graphite will transfer any distance changes between the two anchors to a vibrating wire sensor. In each deformation meter a temperature sensor is included for temperature corrections.

2.4 Embedded strain gages

At some particular locations, Geokon model 4200 strain gages have been installed over single fractures. This model gauge is designed for direct embedment in cast concrete and for installation in grouted boreholes. A steel wire is tensioned between two end blocks and the strain of the wire is measured using the vibrating wire principle.

Deformations in the rock mass induced movements of the hard cement causing the two end blocks to move in relation to each other across a joint, thereby altering the tension in the wire. The tension in the wire is measured by plucking the wire and measuring its resonant frequency of vibration using an electromagnetic coil.

2.5 Cement

Special expansive grout was used to insure that the gage is in complete contact with the surrounding rock. The instruments are grouted in special cement from Denmark named Densitop T2. This cement is chosen to have as similar properties as the rock as possible. The compression strength is 150 Mpa. The coefficient of expansion is approximate 8.5 microstrain/C° that is similar to hard rock as granite and as 85 % of common concrete.

2.6 Registration

Two datalogger type Campbell CR10X have recorded the measurements, which have typically been recorded once every four hours during the period 2005-06-01 to 2005-11-30.

3 Computer processing of field data

3.1 Evaluation of stresses from biaxial stressmeters

The stress changes are evaluated from the measured deformations registered by the vibrating wires.

3.1.1 Radial deformations

Radial deformation for each of the vibrating wires are calculated with the equation:

$$V_r = (R_1 - R_0) * \text{Gagefactor} \quad (\text{mm/ digit})$$

V_r = Radial deformation for each of the vibrating wires

R_1 = Deformation reading in digits (= frequency² / 1000)

R_0 = Deformation zero reading in digits (= frequency² / 1000)

3.1.2 Calculation of deformation to stresses

The magnitude and the direction of the stress changes are determined from the measured radial deformation of the sensor in three directions.

The equations below give the magnitude and the direction of the maximum stress increase and reduction in a plane perpendicular to the borehole axes:

Maximal stress increase

$$p = \frac{1}{2} \left[\frac{1}{3B} \left((2V_{r_1} - V_{r_2} - V_{r_3})^2 + 3(V_{r_2} - V_{r_3})^2 \right)^{\frac{1}{2}} + \frac{1}{3A} (V_{r_1} + V_{r_2} + V_{r_3}) \right]$$

V_{r_1} = Radial deformation for vibrating wire 1

V_{r_2} = Radial deformation for vibrating wire 2

V_{r_3} = Radial deformation for vibrating wire 3

A, B = Coefficients depending on the sensor geometry and the material properties

Maximal stress reduction

$$q = \left[\frac{1}{3A} (V_{r_1} + V_{r_2} + V_{r_3}) - p \right]$$

The angle of the maximal stress increase

The angle in the plane perpendicular to the borehole axes is measured clockwise from the tangential direction of the canister hole.

$$\theta = \frac{1}{2} \cos^{-1} \left[\frac{V_{r_1} - A(p+q)}{B(p-q)} \right]$$

3.2 Evaluation of stress from soft inclusion stress cells

The eight soft inclusion stress cells each contain one vibrating wire which is mounted at a 90° angle from measured direction of stress. Therefore an increase in the readings in digits indicates a reduction on borehole diameter.

The change in the diameter of the borehole is calculated as follows:

$$D = (R_1 - R_0) * G$$

Where R_1 and R_0 are the current and initial readings respectively, in units of digits (frequency² / 1000), and

G is the gage factor in units of (mm/digit)

3.3 Evaluation of deformation

Deformation measurements taken with the Geokon Model 4430 deformation meters were calculated as temperature compensated deformation with the following equations:

$$\text{Deformation}_{\text{corr}} = ((R_1 - R_0) * C) + ((T_1 - T_0) * K) + L_c$$

Where R_1 and R_0 are the current and initial readings respectively, in units of digits (frequency² / 1000),

T_1 and T_0 are the current and initial temperatures respectively in C° ,

C is the gage specific calibration factor

K is the thermal coefficient based on the following equation:

$$K = ((R_1 * M) + B) * C$$

Where $M = 0.000295$, and $B = 1.724$

L_c is the gage length correction based on the following equation:

$$L_c = (17.3 * 10^{-6}) * (\text{Length of the deformation meter} - \text{transducer length}) * (T_1 - T_0)$$

For the gages installed at the Prototype project the transducer length is 267 mm

3.4 Evaluation of strain

Strain measurements taken with the Geokon Model 4200 gages were calculated as temperature compensated strain with the following equation:

$$\mu\epsilon_{true} = (R_1 - R_0) * GF * B + (T_1 - T_0)(C_1 - C_2)$$

$\mu\epsilon_{true}$ = temperature compensated microstrain

R_1 and R_0 = Digits reading

GF = theoretical gage factor

B = batch calibration factor

C_1 and C_2 are the coefficients of expansion of steel and concrete, 12.2 microstrain/ $^{\circ}\text{C}$ and 8.5 microstrain/ $^{\circ}\text{C}$.

3.5 Material parameters

Material parameters used in the calculations are as the following:

- Young's modulus of intact rock 69 Gpa
- Poisson's ratio of intact rock 0.25
- Coefficients of expansion of steel 12.2 microstrain/ $^{\circ}\text{C}$
- Coefficients of expansion of concrete 8.5 microstrain/ $^{\circ}\text{C}$

3.6 Processing

The raw data which have been collected using Multilogger software have been processed using Microsoft Excel software.

4 Results

4.1 Overview and comments

The measurement results are presented graphically for each of the sensors in the following sections for the primary and complementary instruments.

During the presented measuring period there have been some variations in measuring values. The temperature has been rather constant during most of the period except during September and October when the heater for deposition hole 6 was switched off causing a temperature dip from about 50°C to 30°C. During this period most sensors noted a rapid change. In early November the heater was switched back on. The temperature increased, and is still increasing at the end of the period.

Many sensors have shown signs of disturbance or unstable readings up until November 10th when the noise seems to be a lot less also resulting in the return of previously lost sensors. A more detailed investigation is necessary in order to find reasons for this behaviour and change in registration.

It should be noted that the readings are currently uncompensated for the temperature effects.

4.1.1 Biaxial stress meter results

There are still problems with noise, however they have become less and from November 10th the readings are almost free from disturbances. From this date vibrating wires (Vr4, Vr5, and Vr6) in sensor C5 started to present values after 11 months of malfunction. The same thing applies apply to (Vr2) in sensor E5 and (Vr2) in sensor G5 which have been missing for eight and six months respectively. Vibrating wire (Vr2) decreased while (Vr3) increased in sensor E6 at November 10th causing the stress increase/decrease (1-3) to rapidly increase with about 10MPa.

The drop in temperature caused by the switched off/on heater for deposition hole 6 can be seen in sensor E6. The stress changes due to this are however in the range of only a few MPa and are almost not noticeable.

4.1.2 Soft inclusion stress cell

There have been no or very small changes in diameter with a maximum of a 0.005mm increase for sensor D6Soft_1. Generally these sensors are showing steady values with almost no noise throughout the period. The temperature sensors seem to give either unsteady values with a lot of noise or values that are unreasonable low.

4.1.3 Deformation measurements in vertical primary boreholes

The deformation measurements are generally stable but with some noise. The decrease in temperature for deposition hole 6 can be seen in borehole C6, especially in sensor C6Def_3T that are displaying a temperature change of 10°C from about 39°C to 29°C. Towards the end of the period the temperature had again raised to 35°C ending this period with an ongoing increase. During the temperature variation a small compression can be seen.

4.1.4 Strain measurements in vertical primary boreholes

The values are stable but with some noise towards end of the period. The maximum temperature decrease is 7°C. When the temperature drops the compression decreases with a maximum change of 50 micro strain for sensor E6Strain_1 close to deposition hole 6.

4.1.5 Deformation measurements in D5 horizontal complementary boreholes

There are very small or no variations in deformation throughout the period for the deformation sensors around deposition hole 5. The temperature sensors still pick up noise and it is difficult to say if the temperature varies anything. Temperature sensor D5_6_1Def2T are showing an unreasonable large increase of the temperature, probably caused by the noise.

4.1.6 Deformation measurements in D6 horizontal complementary boreholes

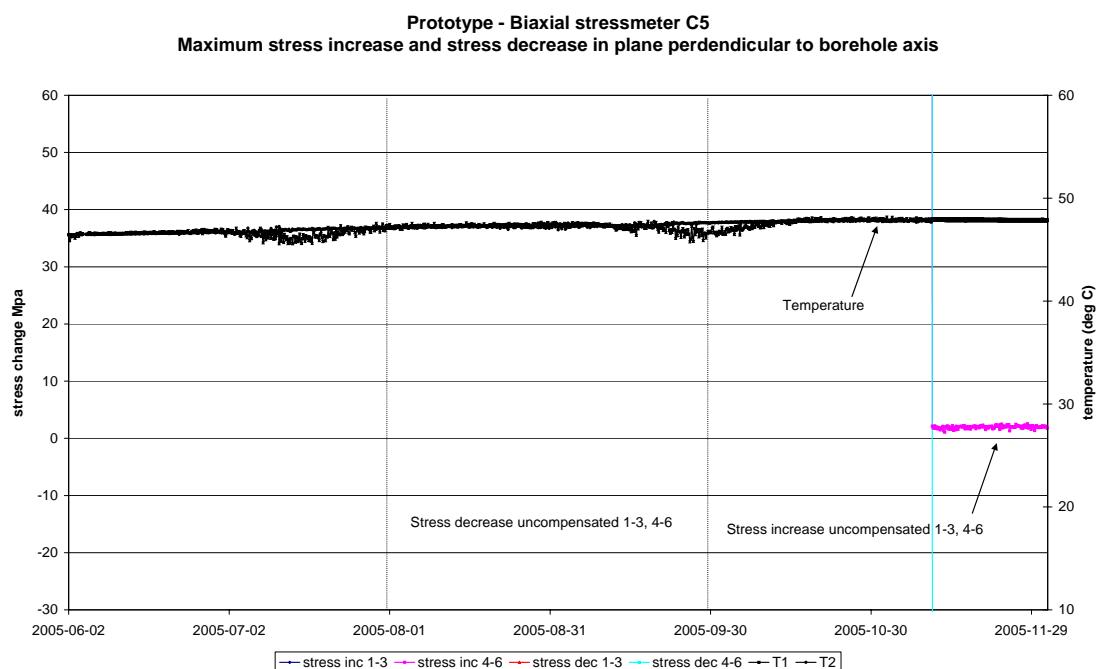

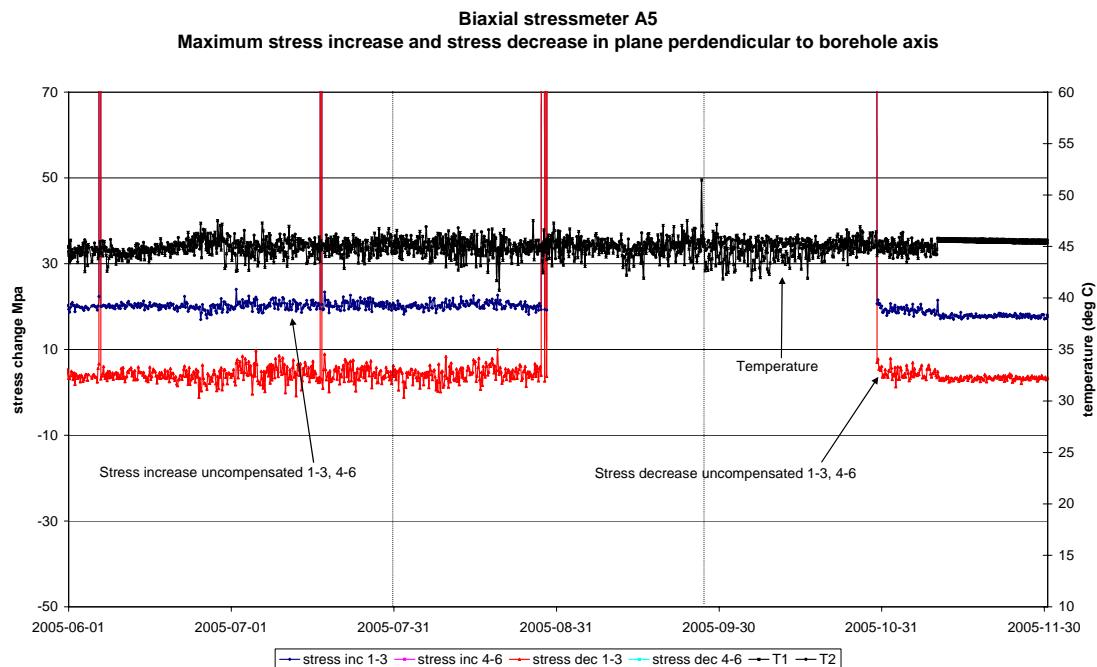

The sensors at 3.5m depth show no or very small signs of disturbance compared to the sensors at 6m depth. It seems like the noise affects the readings less towards the end of the period for the deeper installed sensors. The compression due to the drop in temperature is at the most 0.2mm at sensor D6_6_1Def4.

4.1.7 Strain measurements in complementary boreholes

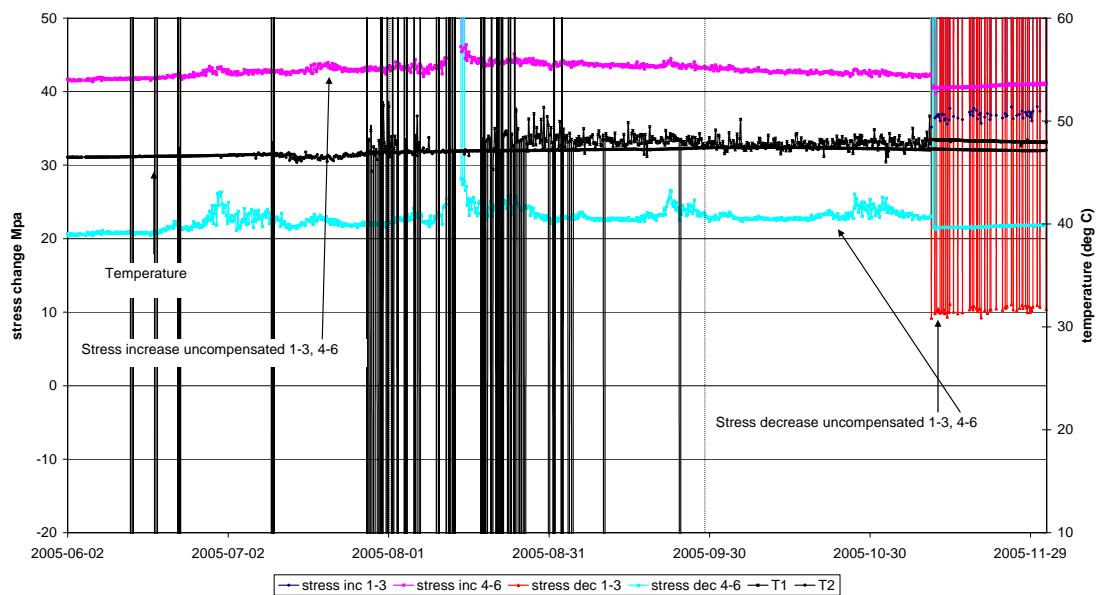

The measurements for borehole D5 are stable with no or very small changes. The maximum tension is 5 micro strains for sensor D5_0_Str_4. The strain measurements from sensors at borehole D6 are difficult to interpret due to noise, but the maximum tension seem to be 15 micro strains. The previously mentioned decrease in temperature can also be seen in these sensors.

Appendix 11

Water pressure in the rock and flow measurements

Rhén I. and Forsmark T., SWECO VIAK AB

Period 2001-09-01 – 2005-12-01

Water pressure measurements in the rockmass

Introduction

The hydraulic properties of the rock, geometry of tunnels and depositions holes, water pressure far away from the tunnels and the hydro-mechanical properties of the backfill and buffer govern the saturation of the buffer and backfill. It is important to measure the water pressure in the rock for the interpretation of the measurements in the buffer and backfill and to sample data useful for the modelling of the saturation process.

A short summary of the instrumentation follows below. For more details see (*Rhén et al, 2001*).

Measurements in the boreholes

A large number of boreholes are instrumented with one or several packers. In all packed-off sections, the water pressure is measured. Each borehole section is connected to a tube of polyamide that via lead-through holes ends in the G-tunnel. All pressure transducers are placed in the G-tunnel to facilitate easy calibration and exchange of transducers that are out of order. The transducers are connected to the HMS system at Äspö Laboratory and it is a flexible system for changing the logging frequency. The maximum scan frequency is 1/second. During periods with no hydraulic tests, preliminary the logging (storing a value in the data base) frequency is 2/hour with an automatic increase of the sampling frequency if the pressure change since last registration is larger than 2kPa. During hydraulic tests, the sampling frequency may be up to 1 logging every 3rd second (maximum logging rate possible).

Instrumentation with bentonite packers in Section I

Section I will be in operation for a long time, possibly up to 20 years, and there will be no access to the instruments in the boreholes for a long period. It was decided to develop a new type of packer that was not dependent of an external pressure to seal-off the borehole sections. These packers are made of compacted bentonite with rubber coverage. For chemical reasons the bentonite is not allowed to be in contact with the surrounding water in the rock mass and therefore the packers have a cover made of polyurethane (PUR-rubber). This rubber also protected the packers against unwanted wetting during transport and installation. After installing all packers in a borehole, the compacted bentonite was wetted to make it swell and expanded against the borehole wall. This packer system is used in 14 boreholes with a length between 12 and 50 meters in the tunnel floor and the walls, see (*Rhén et al, 2001*).

Due to the expected high temperature near the deposition holes two boreholes (KA3574A and KA3576A) were equipped with stainless steel pipes instead of polyamide tubes.

In some sections used for circulation or hydrochemistry sampling purposes in Section I, a dummy is installed to reduce the water-filled volume of the section. Depending on the

purpose the dummies were made either by high-density polyethylene (circulation sections) or PEEK (hydrochemistry sections) material. The dummy consists of two parts, positioned around the centre rod.

The packers were inserted into the borehole with Ø 20 mm massive stainless steel rods. A special designed manual-hoisting rig was used to insert the equipment into the boreholes. When the packers were at their correct position the equipment was attached to a locking device mounted on the tunnel wall at the borehole collar. Before insertion, the equipment was cleaned with a cleaner delivering hot steam (100 °C) at high pressure.

The instrument configuration for the boreholes provided with bentonite packers is summarised in Table 1 and illustrated in Figures 1 and 2.

Table 1 Instrumentation configuration in Section I. “Lead-through”: pipes between the packers.

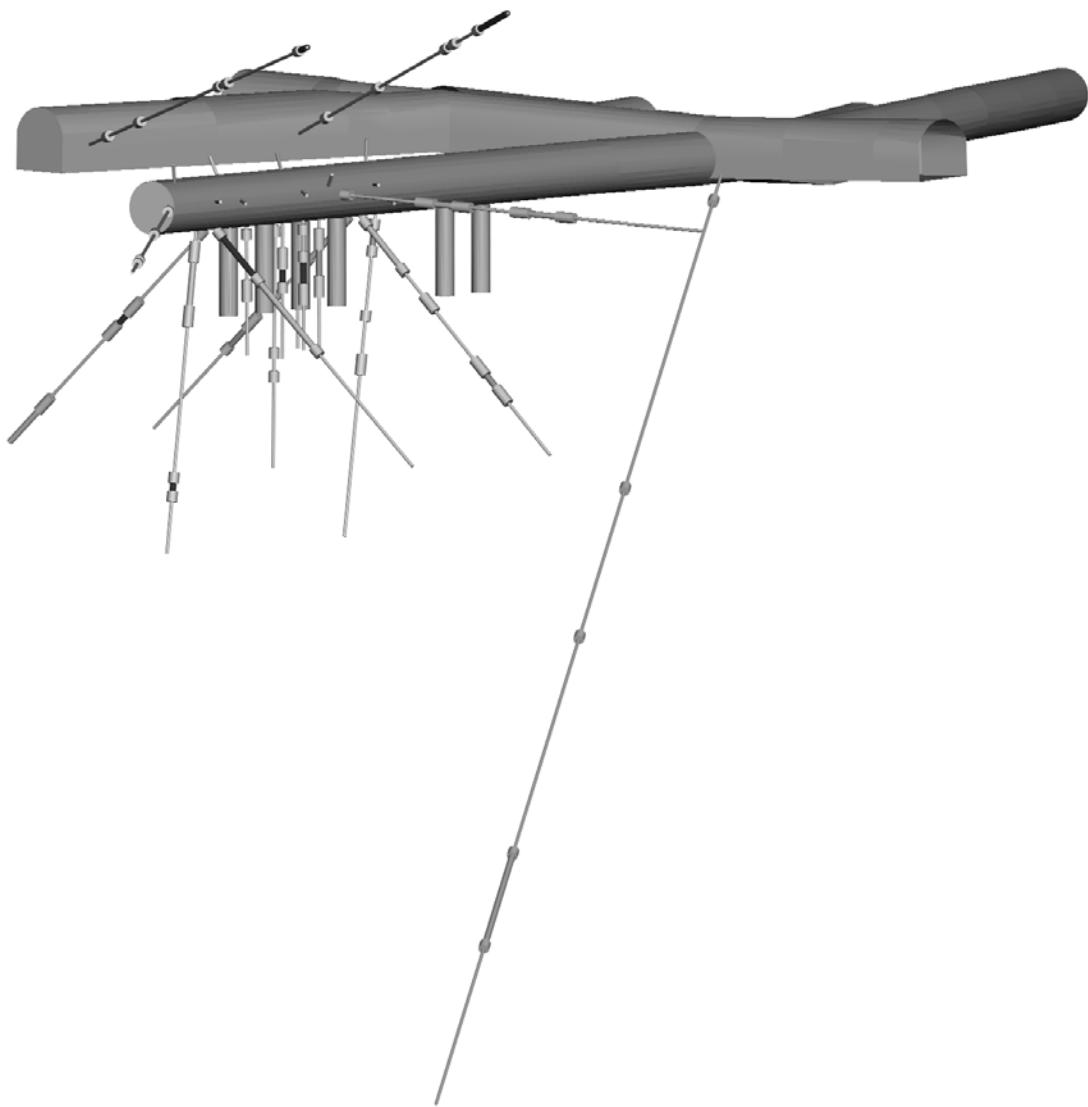

Figure 1. View of the drilled core holes in the Prototype Repository Section I. The length from the I-tunnel to the end of the TBM-tunnel is 90 m. The diameter of the TBM tunnel is 5m and the diameter of the deposition holes is 1.75 m. The depth of the deposition holes is holes is 8.37 m in the centre and 8.15 m along the deposition hole wall. The diameter of the core holes is 76 mm except for the short core holes in the roof of the TBM tunnel that have a diameter of 56 mm. The monitoring boreholes used in the presentation in this report are located in the inner part of the tunnel surrounding the area with the four innermost canister holes. Also included are two holes drilled from the G-tunnel and the long hole KA3510A drilled from the main tunnel.

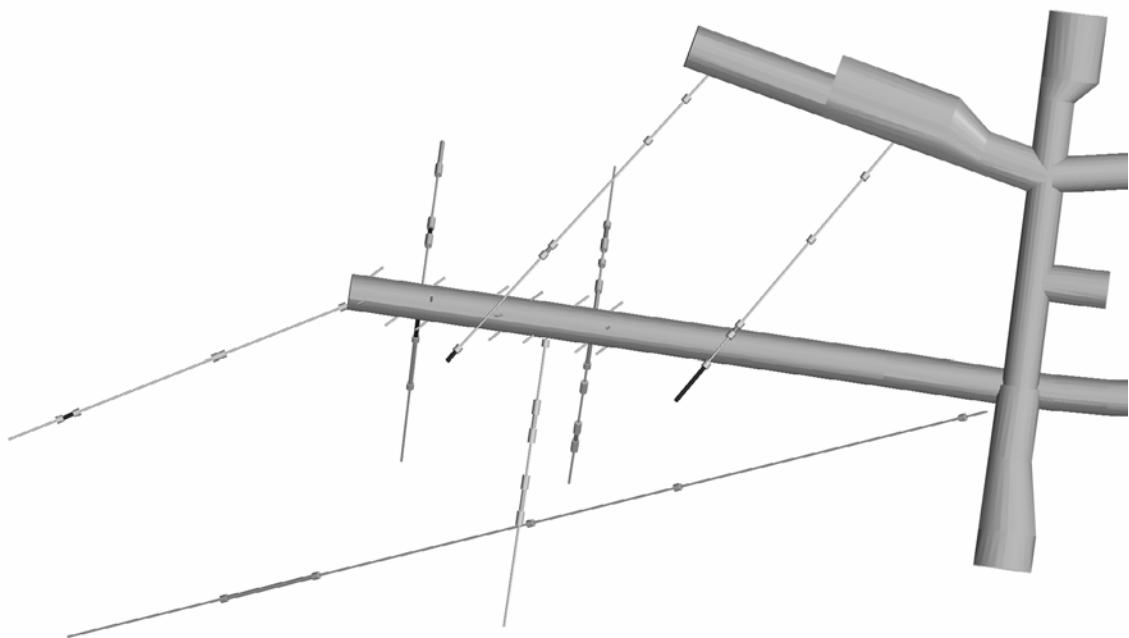

Figure 2. Overview of Sektion I in Prototype Repository

Instrumentation with hydraulic packers in Section II

Fifteen boreholes are equipped with hydraulically expanded packers of one meters length to seal off at most five sections in one borehole. In ten of these boreholes one section also is instrumented with hydro-mechanical equipment adapted to measure small deformations in the solid rock and over selected fractures. Another borehole in the G-tunnel is instrumented with HM equipment as a reference. The borehole was drilled in the north tunnel wall and is not expected to be influenced by the stress changes around the Prototype tunnel.

Table 2 Instrumentation configuration in Section II. “Lead-through”: pipes between the packers.

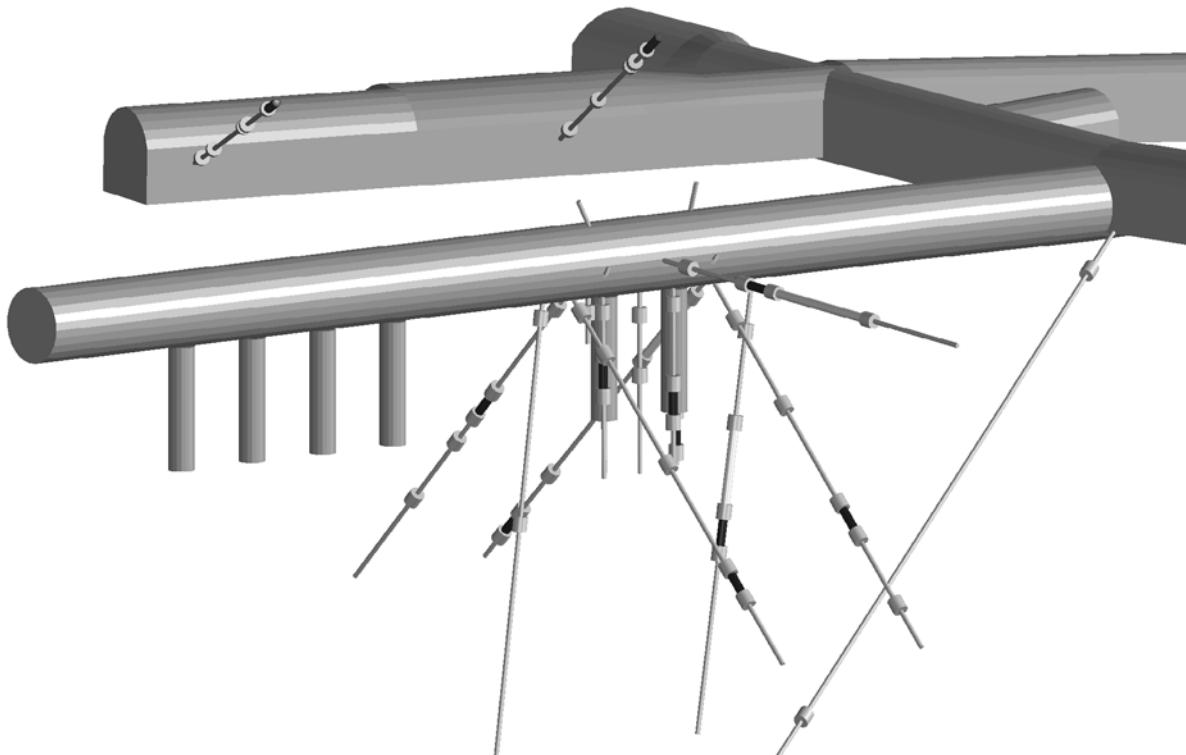

Figure 3 View of the drilled core holes in the Prototype Repository Section II. The length from the I-tunnel to the end of the TBM-tunnel is 90 m. The diameter of the TBM tunnel is 5m and the diameter of the deposition holes is 1.75 m. The depth of the deposition holes is 8.37 m in the centre and 8.15 m along the deposition hole wall. The diameter of the core holes is 76 mm except for the short core holes in the roof of the TBM tunnel that have a diameter of 56 mm. The monitoring boreholes used in the presentation in this report are located in the inner part of the tunnel surrounding the area with the four innermost canister holes. Also included are two holes drilled from the G-tunnel and the long hole KA3510A drilled from the main tunnel.

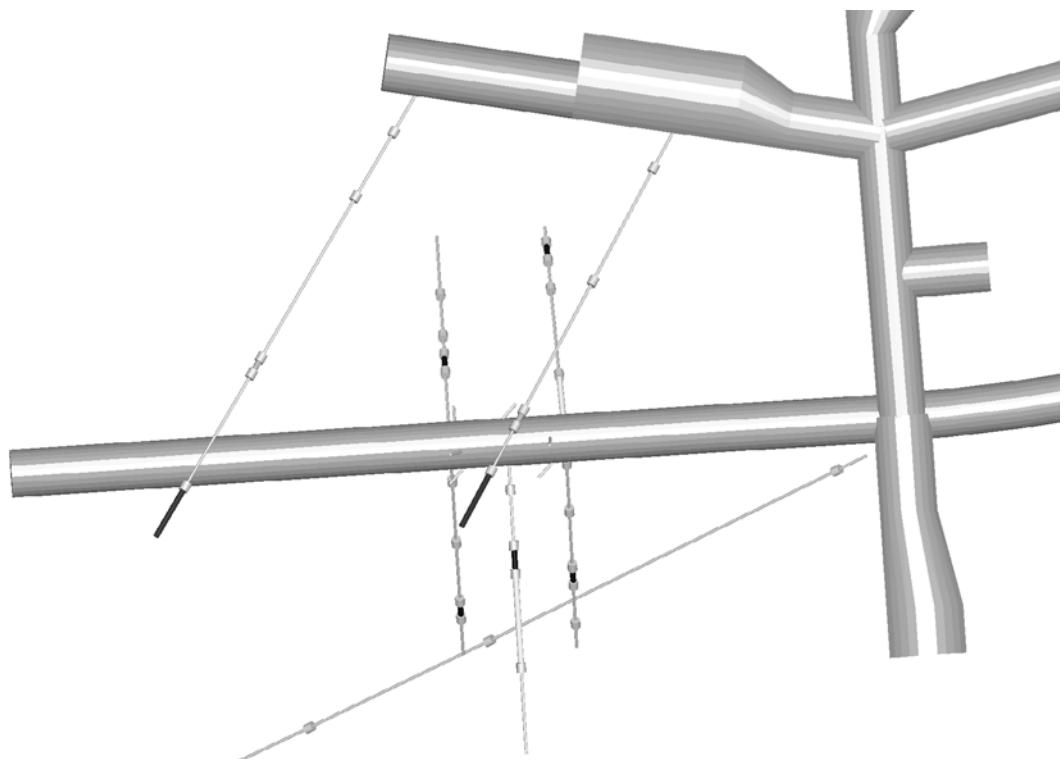

Figure 4 Overview of Sektion II in Prototype Repository

Instrumentation with mechanical packers

Twenty-two short boreholes (2 m) in the tunnel roof and walls are equipped with mechanical packers, see Table 3. After insertion into the hole, the pulling of a nut on the centre pipe expanded the packer. Since these holes are directed upwards, the de-aeration required an extra lead-through connected to a tube ending in the innermost part of the borehole. The de-aeration was made during the backfilling and in boreholes with very little flow the de-aeration was made by filling water through the outer tube.

Table 3 Boreholes instrumented with mechanical packers
 (“Inclination”: inclination of the borehole)

Pressure measurements

In this section pressure measurements of all monitored holes in the Prototype repository is shown in plots below. The pressure values plotted are daily mean values. The definition of day 0 is the day the heating of canister 1 started, i.e. 2001-09-17. In *Table 5* the dates of the starting of the heaters in all canisters are presented.

Table 5 Starting of heaters in canisters

Canister in deposition hole	Date
1 (DA3587G)	2001-09-17
2 (DA3581G)	2001-09-24
3 (DA3575G)	2001-11-10
4 (DA3569G)	2001-11-24
5 (DA3551G)	2003-05-08
6 (DA3545G)	2003-05-23

The position of pressure measurement is indicated for all observation sections.

In general sections close to the prototype rock wall indicate lower pressure head than further away from the prototype.

In the longer holes the section closest to the wall have a lower head than sections deeper into the rockmass.

A pressure drop 2002-05-07 for most of the observation sections are shown in the plots. The most major pressure change happens in the lowest section of KA3566G02 (approx. 70 m) but are also clearly visible for section 2-4 of the same borehole. The pressure recovered during the evening of 2002-12-02. The cause for the pressure change is unknown.

Several sections have had a slight decreasing trend since the summer of 2002. This trend have in most cases been discontinued after 2004-11-01.

The instrumentation of boreholes in Section II started 2002-11-06 and continued until the beginning of December 2002. Several sections indicate a pressure drop around 2002-11-11 which probably is caused by the installation work.

The sections of KA3510A show a drop of pressure during the first week of December 2002. The pressure is quickly re-established. Probably the cause for this was the on-going monitoring work in Section II.

During the period 2003-05-08 until 2003-05-15 a total of 19 hydraulic tests were done in several of the boreholes in Section I and II. The tests caused groundwater pressure interference in the whole of the prototype repository area. Since the tests were mostly short-time tests it is only shown in some of the borehole section plots.

During the summer 2003 (2003-07-13 to 2003-08-05) no pressure data was recorded. In some of the long boreholes inclined to the south of the prototype show a pressure drop in mid-August.

The packers in KA3550G01 were deflated 2003-08-18 and has not been possible to re-inflate again. The reason is probably a tube leakage.

Hydraulic single hole tests were done in nine boreholes during 2003-10-21 – 10-23. The tests caused groundwater pressure interference in the whole of the prototype repository area. Since the tests were mostly short-time tests it is only shown in some of the borehole section plots.

The packers in five boreholes were deflated around Oct 30 – Nov 1, 2003. This was probably generated by a tube leakage which in its turn emptied the water in the pressure vessel and finally emptied the gas tube connected to it. The boreholes whose packers were deflated were KA3542G01, KA3542G02, KA3544G01 and KA3548A01. It was possible to inflate the packers in three of the four boreholes on 2003-11-10. It was not possible to restore the status of KA3544G01. This pressure drop is observed in several other borehole observation sections.

Hydraulic single hole tests were done in eight boreholes during 2004-02-02 – 02-04. The tests caused groundwater pressure interference in the whole of the prototype repository area. Since the tests were mostly short-time tests it is only shown in some of the borehole section plots.

A pressure drop of around 700 kPa in KA3566G01:4 is observed 2004-02-25. It remained so for some weeks before recovering, but dropped again in May and remains that way at the end of the month. This pattern was observed in this section during the spring 2003. The following investigation showed a faulty data-scan coupling (corrosion) which were replaced 2004-08-10.

Hydraulic single hole tests were done in eight boreholes during 2004-08-11 – 08-18. The tests caused groundwater pressure interference in the whole of the prototype repository area. Since the tests were mostly short-time tests it is only shown in some of the borehole section plots.

During the period 2005-01-19 until 2005-01-28 a total of 26 hydraulic tests were done in several of the boreholes in Section I and II. The tests caused groundwater pressure interference in the whole of the prototype repository area. Since the tests were mostly short-time tests it is only shown in some of the borehole section plots.

During week 36, starting 2005-09-05, several boreholes have a rather sudden drop in pressure which does not recover immediately. The reason is not known yet.

During week 39, starting 2005-10-01, pressure in KA3557G decreased rather suddenly. This was due to an empty gas pressure vessel, which has been replaced now (January 2006).

Hydraulic single hole tests were done in eight boreholes during 2005-11-28 – 12-02. A total of 17 tests were done. The tests caused groundwater pressure interference in the whole of the prototype repository area. Since the tests were mostly short-time tests it is only shown in some of the borehole section plots.

In Table 6 the pressure sensor status 2005-12-01 is estimated based on pressure head data. It is to be noted as an estimation only.

Drainage of Section I

The drainage system in Section I was shut down 2004-11-01. It resulted in a major pressure increase in most borehole sections close to the prototype tunnel. The pressure increased until 2004-12-06.

The drained water amount was approximately 2.5 L/min. The flowrate of weir MG0004G decreased accordingly with the same order of magnitude after November 1.

The drainage system was re-opened 2004-12-06 due to electrical problems with the canister heaters. It is still open (2005-12-01). The pressure in most borehole sections within Section I decreases rapidly again while the pressures in Section II decreases more slowly.

Packer functionality status in Section II

The packers are of the type PU53 or PU72. All packers have an inflation length of one meter and the minimum and maximum packer expansion pressure is 6.5 bar and 65 bar respectively. They are expanded by means of water, pressurised by nitrogen gas in a pressure vessel. A regulator controls the magnitude of the inflation pressure. The stainless steel pressure vessel is connected to the packers by a high-pressure 6/4-mm polyamide tube, type Tecalan. A check valve unit with a manometer is mounted on the packer inflation line. In order to avoid accidental deflation the check valve unit also includes a stop valve.

In Table 7 below are listed the borehole packers that have ceased to function for some reason.

Deformation measurements in Section II

Deformation measurements of fractures in borehole sections with Hydro-Mechanical anchors in Section II are on-going but no results are available yet.

Flow measurements

Earlier estimations and measurements of inleaking ground water amounts to the tunnel system are presented in (*Forsmark T, Rhén I, 2001*) and (*Rhén I, Forsmark T, 2001*).

Data from eight flow weirs are presented in this data report.

A weir at the tunnel G opening measures the inleaking amounts from this tunnel. The weir is named MG0004G. The pumped water amounts from Section I mentioned above was prior to November 1, 2004, when the drainage of Section I was closed down, included in the rates from this weir station which is clearly shown in the diagram below.

The weir MF0061G halfway down tunnel F measures the inleaking amounts from the north part of tunnel J (J+) and the first half of tunnel F, see plot of this weir. Early in the presented period, autumn 2001, inleaking water from tunnel G was led to tunnel F and weir MF0061G thereby to some extent explaining the high flowrate during that period.

The weir MA3426G measures the flow rates from the south part of tunnel J, tunnel I and tunnel A chainage 3426 – 3600 m.

In December 2003 three new flow measurement weirs were constructed in the A-tunnel outside Section II plug. They are called MA3515G, MA3525G and MA3535G.

Continous measurement is done since the spring of 2004. Manual measurements done in december 2003 show a flowrate for MA3515G of 0.175 – 0.19 L/min, for MA3525G of 1.15 – 1.25 L/min and for MA3535G of 0.38 – 0.45 L/min. The increase of flow during October 2004 was caused by yet unknown causes, but it is believed that the final

grouting that was done around Plug 2 October 8, 2004 is the cause to it. The flow rates have now decreased once again.

Two weirs have, during the winter 2004/2005, been constructed inside niches I and J. They are called MI0008G and MJ0033G respectively. MI0008G is included in the continuously measurement program while MJ0033G is measured manually approximately every fortnight.

Water sampling

Water sampling for chemical analysis have been done at several occasions, see *Table 8*. Each one of them may have an short-lived effect on the hydrostatic pressure in the rockmass. In some cases the flowing of a section continued for several days and the following pressure response is clearly shown in the subsequent plot.

Table 8 Water sampling dates in boreholes close to the Prototype Repository. Start and stop of times are for the flowing of the section.

Quick guide

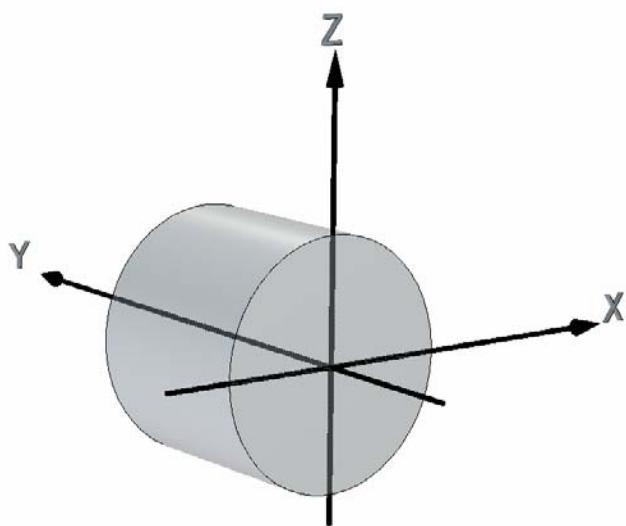

Transducers in the backfill

Gauge type	WBA 10008 (E2 / -0.5 /-0.3 /3566)
Gauge number	<input type="text"/>
Section (E=above dep. hole F=Between dep. hole)	<input type="text"/>
x coordinate (m)	<input type="text"/>
z coordinate (m)	<input type="text"/>
y coordinate (m)	<input type="text"/>

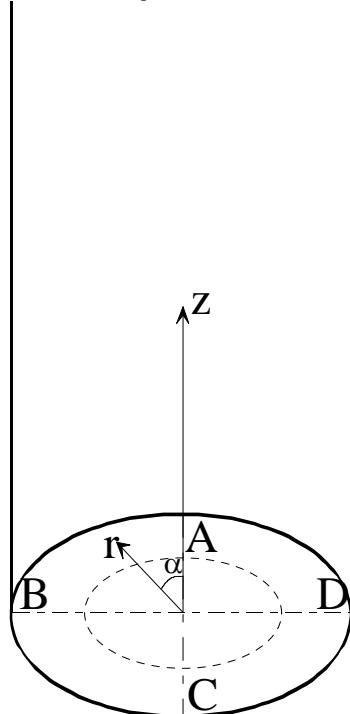

Transducers in dep. holes 1, 3,5 and 6 and in the rock

Gauge type	TBU 10004 (2.75\ 270° 2.0)
Gauge number	<input type="text"/>
z coordinate (m)	<input type="text"/>
α coordinate(degrees)	<input type="text"/>
r coordinate (m)	<input type="text"/>

Coordinate system in backfill

Coordinate system in dep. holes

End of tunnel at	Y =3599.8 m
Center dep.hole 1.at	Y =3587 m
Center dep.hole 2 at	Y =3581 m
Center dep.hole 3 at	Y =3575 m
Center dep.hole 4 at	Y =3569 m
Inner plug surface at	Y=3561.4 m
Center dep.hole 5 at	Y =3551 m
Center dep.hole 6 at	Y =3545 m
Outer plug surface at	Y=3538.6 m
Tunnel radius	Z=X =2.5 m

Tunnel direction	C-A
Bottom of hole	Z=0
Bottom of canister	Z=0.5
Top of canister	Z=5.400
Upper buffer surface	Z=7.125
Dep. hole radius	r=0.875
Canister radius	r=0.525
