Abstract

Uniaxial compression tests, containing the complete loading response beyond compressive failure, so called post-failure tests, were carried out on water saturated cylindrical specimens of intact rock taken from drill cores from the boreholes KLX05 and KLX13A in Oskarshamn. Sixteen specimens at three depth levels ranging between 583–588 m, 725–738 m respectively 792–796 m borehole length were taken from borehole KLX05 and one specimen at 252 m borehole length was taken from borehole KLX13A. The rock types from borehole KLX05 were quartz monzodiotite (583–588 m and 792–796 m) and fine-grained granite (725–738 m) and from borehole KLX13A fine-grained granite. The elastic properties, represented by Young's modulus and the Poisson ratio, and the uniaxial compressive strength were deduced from these tests. The wet density of the specimens was determined before the mechanical tests. The specimens were photographed before as well as after the mechanical testing.

The measured densities for the water saturated specimens from borehole KLX05 were in the range 2,650–2,810 kg/m³ yielding a mean value of 2,732 kg/m³, whereas the peak values of the axial compressive stress were in the range 161.3–356.4 MPa with a mean value of 237.0 MPa. The elastic parameters were determined at a load corresponding to 50% of the failure load, and it was found that Young's modulus was in the range 69.2–79.1 GPa with a mean value of 73.5 GPa and that the Poisson ratio was in the range of 0.25–0.33 with a mean value of 0.28.

The measured density for the water saturated specimen from borehole KLX13A was 2,650 kg/m³, whereas the peak value of the axial compressive stress was 320.1 MPa. The elastic parameters were determined at a load corresponding to 50% of the failure load, and it was found that Young's modulus was 69.4 GPa and that the Poisson ratio was 0.32.

The mechanical tests revealed that the material in the specimens responded in a brittle way.

Sammanfattning

Enaxiella kompressionsprov med belastning upp till brott och efter brott, så kallade "postfailure tests", har genomförts på vattenmättade cylindriska provobjekt av intakt berg tagna från borrkärnor från borrhålen KLX05 och KLX13A i Oskarshamn. Sexton prover vid tre djupnivåer, 583–588 m, 725–738 m respektive 792–796 m borrhålslängd har tagits ut från borrhål KLX05 och ett prov vid 252 m borrhålslängd har tagits ut från borrhål KLX13A. Bergarterna från borrhål KLX05 var kvartsmonzodiorit (583–588 m och 792–796 m) och finkornig granit (725–738 m) och från borrhål KLX13A finkornig granit. De elastiska egenskaperna, representerade av elasticitetsmodulen och Poissons tal, har bestämts ur försöken. Bergmaterialets densitet i vått tillstånd hos proverna mättes upp före de mekaniska proven. Provobjekten fotograferades såväl före som efter de mekaniska proven.

Den uppmätta densiteten hos de vattenmättade proven från borrhål KLX05 uppgick till mellan 2 650–2 810 kg/m³ med ett medelvärde på 2 732 kg/m³. Toppvärdena för den kompressiva axiella spänningen låg mellan 161,3–356,4 MPa med ett medelvärde på 237,0 MPa. De elastiska parametrarna bestämdes vid en last motsvarande 50 % av högsta värdet på lasten, vilket gav en elasticitetsmodul mellan 69,2–79,1 GPa med ett medelvärde på 73,5 GPa och Poissons tal mellan 0,25–0,33 med ett medelvärde på 0,28.

Den uppmätta densiteten hos det vattenmättade provet från borrhål KLX13A uppgick till 2 650 kg/m³. Toppvärdet för den kompressiva axiella spänningen låg på 320,1 MPa. De elastiska parametrarna bestämdes vid en last motsvarande 50 % av högsta värdet på lasten, vilket gav en elasticitetsmodul på 69,4 GPa och Poissons tal på 0,32.

Vid belastningsförsöken kunde man se att materialet i provobjekten hade ett sprött beteende.

1 Introduction

This document reports performance and results of uniaxial compression tests, with loading beyond the failure point into the post-failure regime, on water-saturated drill core specimens sampled from boreholes KLX05 and KLX13A at Oskarshamn, see map in Figure 1-1. The tests were carried out in the material and rock mechanics laboratories at the Department of Building Technology and Mechanics at the Swedish National Testing and Research Institute (SP). The activity is part of the site investigation programme at Oskarshamn managed by SKB (The Swedish Nuclear Fuel and Waste Management Company).

The controlling documents for the activity are listed in Table 1-1. Both Activity Plan and Method Descriptions are SKB's internal controlling documents, whereas the Quality Plan referred to in the table is an SP internal controlling document.

Borehole KLX05 is of a type called "long-hole" with a total length of c 1,000 m located in the south region within the Laxemar area at the site investigation. Borehole KLX13A is a medium length borehole of c 600 m located in the north-west region within the Laxemar area at the site investigation. The actual positions of the two boreholes are shown in Figure 1-1.

SKB supplied SP with rock cores which arrived at SP in October 2006 and were tested during December 2006. Cylindrical specimens were cut from the cores and selected based on the preliminary core logging with the aim to investigate the properties of the rock types quartz monzodiorite (501036) and fine-grained granite (511058) in borehole KLX05 and fine-grained granite (511058) in borehole KLX13A. The method description SKB MD 190.001 was followed both for sampling and for the uniaxial compression tests, whereas the density determinations were performed in compliance with method description SKB MD 160.002.

As to the specimen preparation, the end surfaces of the specimens were grinded in order to comply with the required shape tolerances. The specimens were put in water and kept stored in water for a minimum of 7 days, up to density determination and uniaxial testing. This yields a water saturation, which is intended to resemble the in situ moisture condition. The density was determined on each specimen and the uniaxial compression tests were carried out at this moisture condition. The specimens were photographed before and after the mechanical testing.

The uniaxial compression tests were carried out using radial strain as the feed-back signal in order to obtain the complete response in the post-failure regime on brittle specimens as described in the method description SKB MD 190.001 and in the ISRM suggested method /1/. The axial ε_a and radial strain ε_r together with the axial stress σ_a were recorded during the test. The peak value of the axial compressive stress σ_c was determined at each test. Furthermore, two elasticity parameters, Young's modulus *E* and Poisson ratio *v*, were deduced from the tangent properties at 50% of the peak load. Diagrams with the volumetric and crack volumetric strain versus axial stress are reported. These diagrams can be used to determine crack initiation stress σ_i and the crack damage stress σ_d , cf /2, 3/.

2 Objective

The purpose of the testing is to determine the uniaxial compressive strength and the elastic properties, represented by Young's modulus and the Poisson ratio, of cylindrical specimens of intact rock sampled from drill cores. Moreover, the specimens had a water content corresponding to the in situ conditions. The loading was carried out into the post-failure regime in order to study the mechanical behaviour of the rock after cracking, thereby enabling determination of the brittleness and residual strength.

The results from the tests are to be used in the site descriptive rock mechanics model, which will be established for the candidate area selected for site investigations at Oskarshamn.

3 Equipment

3.1 Specimen preparation and density measurement

A circular saw with a diamond blade was used to cut the specimens to their final lengths. The surfaces were then grinded after cutting in a grinding machine in order to achieve a high-quality surface for the axial loading that complies with the required tolerances. The measurements of the specimen dimensions were made with a sliding calliper. Furthermore, the tolerances were checked by means of a dial indicator and a stone face plate. The specimen preparation is carried out in accordance with ASTM 4543-01 /4/.

The specimens and the water were weighed using a scale for weight measurements. A thermometer was used for the water temperature measurement. The calculated wet density was determined with an uncertainty of $\pm 4 \text{ kg/m}^3$.

3.2 Mechanical testing

The mechanical tests were carried out in a servo controlled testing machine specially designed for rock tests, see Figure 3-1. The system consists of a load frame, a hydraulic pump unit, a controller unit and various sensors. The communication with the controller unit is accomplished by means of special testing software run on a PC connected to the controller. The load frame is characterized by a high stiffness and is supplied with a fast responding actuator, cf the ISRM suggested method /1/.

Figure 3-1. Rock testing system. From left: Digital controller unit, pressure cabinet (used for triaxial tests) and load frame. The PC with the test software (not shown in the picture) is placed on the left hand side of the controller unit.

The stiffness of the various components of the loading chain in the load frame has been optimized in order to obtain a high total stiffness. This includes the load frame, load cell, load platens and piston, as well as having a minimum amount of hydraulic oil in the cylinder. Furthermore, the sensors, the controller and the servo valve are rapidly responding components. The axial load is determined using a load cell, which has a maximum capacity of 1.5 MN. The uncertainty of the load measurement is less than 1%.

The axial and circumferential (radial) deformations of the rock specimens were measured. The rock deformation measurement systems are based on miniature LVDTs with a measurement range of ± 2.5 mm. The relative error for the LVDTs is less than 0.6% within a 1 mm range for the axial deformation measurements and less than 1.3% within a 3 mm range for the circumferential deformation measurement. The LVDTs have been calibrated by means of a micrometer.

Two independent systems were used for the axial deformation measurement in order to obtain two comparative results. The first system (S1), see Figure 3-2, comprises two aluminium rings attached on the specimen, placed at ¹/₄ and ³/₄ of the specimen height. Two LVDTs mounted on the rings are used to measure the distance change between the rings on opposite sides of the specimen. As to the attachment, two rubber bands made of a thin rubber hose with 0.5 mm thickness are first mounted on the specimen right under where the two rings are to be positioned. The rings are supplied with three adjustable spring-loaded screws, each with a rounded tip pointing on the specimen with 120 degrees division. The screw tips are thus pressing on the rubber band, when the rings are mounted. The second system (S2), see Figure 3-3, consists of two aluminium plates clamped around the circular loading platens of steel on top and on bottom of the specimen. Two LVDTs, mounted on the plates, measure the distance change between these plates at opposite sides of the specimen at corresponding positions as for the first measurement system (S1).

The radial deformation was obtained by using a chain mounted around the specimen at midheight, see Figures 3-2 and 3-3. The change of the chain-opening gap was measured by means of one LVDT and the circumferential, and thereby also the radial deformation could be obtained. See Appendix A.

The specimens were photographed with a 4.0 Mega pixel digital camera at highest resolution and the photographs were stored in a jpeg-format.

Figure 3-2. Left: Specimen with two rubber bands. Devices for local axial and circumferential deformation measurements attached on the specimen. Right: Rings and LVDTs for local axial deformation measurement.

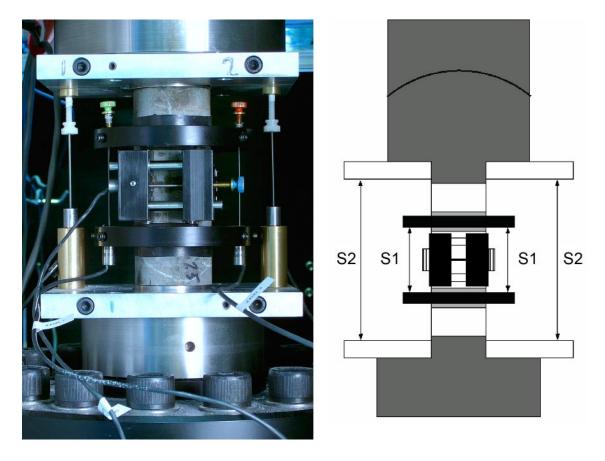

Figure 3-3. Left: Specimen inserted between the loading platens. The two separate axial deformation measurement devices can be seen: system (S1) that measures the local axial deformation (rings), and system (S2) that measures the deformation between the aluminium plates (total deformation). Right: Principal sketch showing the two systems used for the axial deformation measurements.

4 Execution

The water saturation and determination of the density of the wet specimens were made in accordance with the method description SKB MD 160.002 (SKB internal controlling document). This includes determination of density in accordance to ISRM /5/ and water saturation by SS EN 13755 /6/. The uniaxial compression tests were carried out in compliance with the method description SKB MD 190.001 (SKB internal controlling document). The test method is based on ISRM suggested method /1/.

4.1 Description of the specimens

The rock type characterisation was made according to Stråhle /7/ using the SKB mapping system (Boremap). The identification marks, upper and lower sampling depth (Secup and Seclow) and the rock type are shown in Tables 4-1 (KLX05) and 4-2 (KLX13A). The finegrained granite specimens from borehole KLX05A have a foliated material structure along the specimen axis.

Identification	Adj secup (m)	Adj seclow (m)	Rock type/occurrence
KLX05-113-2	583.45	583.59	Quartz monzodiorite (501036)

4.2 Specimen preparation and density measurement

The temperature of the water was 19.5°C, which equals to a water density of 998.3 kg/m³, when the determination of the wet density of the rock specimens was carried out. Further, the specimens had been stored during 7 days in water when the density was determined.

An overview of the activities during the specimen preparation is shown in the step-by-step description in Table 4-3.

4.3 Mechanical testing

The specimens had been stored 8–14 days in water when the uniaxial compression tests were carried out. The functionality of the testing system was checked before starting the tests. A check-list was filled in successively during the work in order to confirm that the different specified steps had been carried out. Moreover, comments were made upon observations made during the mechanical testing that are relevant for interpretation of the results. The check-list form is an SP internal quality document.

An overview of the activities during the mechanical testing is shown in the step-by-step description in Table 4-4.

4.4 Data handling

The test results were exported as text files from the test software and stored in a file server on the SP computer network after each completed test. The main data processing, in which the elastic moduli were computed and the peak stress was determined, has been carried out using the program MATLAB /8/. Moreover, MATLAB was used to produce the diagrams shown in Section 5.1 and in Appendix B. The summary of results in Section 5.2 with tables containing mean value and standard deviation of the different parameters and diagrams were provided using MS Excel. MS Excel was also used for reporting data to the SICADA database.

Table 4-3	Activities	during	the	specimen	preparation.
-----------	------------	--------	-----	----------	--------------

Step	Activity
1	The drill cores were marked where the specimens are to be taken.
2	The specimens were cut to the specified length according to markings and the cutting surfaces were grinded.
3	The tolerances were checked: parallel and perpendicular end surfaces, smooth and straight circumferential surface.
4	The diameter and height were measured three times each. The respectively mean value determines the dimensions that are reported.
5	The specimens were then water saturated according to the method described in SKB MD 160.002 and were stored for minimum 7 days in water, whereupon the wet density was determined.

Step	Activity
1	Digital photos were taken on each specimen before the mechanical testing.
2	Devices for measuring axial and circumferential deformations were attached to the specimen.
3	The specimen was put in place and centred between the frame loading platens.
4	The core on each LVDT was adjusted by means of a set screw to the right initial position. This was done so that the optimal range of the LVDTs can be used for the deformation measurement.
5	The frame piston was brought down into contact with the specimen with a force corresponding to 1.0 MPa axial stress.
6	A load cycle with loading up to 5 MPa and unloading to 1.0 MPa was conducted in order to settle possible contact gaps in the spherical seat in the piston and between the rock specimen and the loading platens.
7	The centring was checked again.
8	The deformation measurement channels were zeroed in the test software.
9	The loading was started and the initial loading rate was set to a radial strain rate of –0.025%/min. The loading rate was increased after reaching the post-failure region. This was done in order to prevent the total time for the test to become too long.
10	The test was stopped either manually when the test had proceeded long enough to reveal the post- failure behaviour, or after severe cracking had occurred and it was judged that very little residual axial loading capacity was left in the specimen.
11	Digital photos were taken on each specimen after the mechanical testing.

 Table 4-4. Activities during the mechanical testing.

4.5 Analyses and interpretation

As to the definition of the different results parameters we begin with the axial stress σ_a , which is defined as

$$\sigma_{\rm a} = \frac{F_{\rm a}}{A}$$

where F_a is the axial force acting on the specimen, and A is the specimen cross section area. The peak value of the axial stress during a test is representing the uniaxial compressive strength σ_c in the results presentation.

The average value of the two axial displacement measurements on opposite sides of the specimen is used for the axial strain calculation, cf Figure 3-3. In the first measurement system (S1), the recorded deformation represents a local axial deformation δ_{local} between the points at ¹/₄ and ³/₄ height. A local axial strain is defined as

 $\varepsilon_{a,local} = \delta_{local} / L_{local}$

where L_{local} is the distance between the rings before loading.

In the second measurement system (S2), the recorded displacement corresponds to a total deformation that, in addition to total rock deformation, also contains the local deformations that occur in the contact between the rock and the loading platens, and further it also contains the deformation of the steel loading platens at each side of the specimen ends. The average value of the two total deformation measurements on opposite sides of the specimen is defined as the total deformation δ_{total} . An axial strain based on the total of the deformation is defined as

 $\varepsilon_{\rm a,total} = \delta_{\rm total} / L_{\rm total}$

where L_{total} is the height of the rock specimen.

The radial deformation is measured by means of a chain mounted around the specimen at midheight, cf Figures 3-2 and 3-3. The change of chain opening gap is measured by means of one LVDT. This measurement is used to compute the radial strain ε_r , see Appendix A. Moreover, the volumetric strain ε_{vol} is defined as

$$\varepsilon_{\rm vol} = \varepsilon_{\rm a} + 2\varepsilon_{\rm r}$$

The stresses and the strains are defined as positive in compressive loading and deformation. The elasticity parameters are defined by the tangent Young's modulus E and tangent Poisson ratio v as

$$E = \frac{\sigma_{a}(0.60 \sigma_{c}) - \sigma_{a}(0.40 \sigma_{c})}{\varepsilon_{a}(0.60 \sigma_{c}) - \varepsilon_{a}(0.40 \sigma_{c})}$$
$$v = -\frac{\varepsilon_{r}(0.60 \sigma_{c}) - \varepsilon_{r}(0.40 \sigma_{c})}{\varepsilon_{a}(0.60 \sigma_{c}) - \varepsilon_{a}(0.40 \sigma_{c})}$$

The tangents were evaluated with values corresponding to an axial load between 40% and 60% of the axial peak stress σ_c .

Two important observations can be made from the results:

- (i) The results based on the total axial deformation measurement (S2) display a lower axial stiffness, i.e. a lower value on Young's modulus, than in the case when the results are based on the local axial deformation measurement (S1). This is due to the additional deformations from the contact interface between the rock specimen and the steel loading platens and also due to the deformation of the loading platens themselves.
- (ii) It can be seen that the response differs qualitatively between the results obtained with the local axial deformation measurement system (S1) and the system that measures total axial deformation (S2). In some cases the post-peak response obtained with the local deformation measurement system seems not to be physically correct. This can be due to a number of reasons, e.g. that a crack caused a localized deformation, see Figure 4-1. Another explanation could be that the rings attached to the specimens have slightly slipped or moved, for example if a crack was formed nearby one of the attachment points.

It is reasonable to assume that results based on the local axial deformation measurement (S1) are fairly accurate up to the formation of the first macro-cracks or up to the peak load, but not thereafter. However, the results obtained with the total axial deformation measurement (S2) seem to be qualitatively correct after failure. We will therefore report the results based on the total axial deformation measurement, but carry out a correction of those results as described below in order to obtain overall good results.

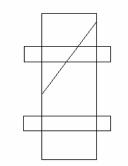

Figure 4-1. Example of cracking that may cause results that are difficult to interpret with a local deformation measurement.

The total axial deformation δ_{total} measured by (S2) is a summation of several deformations

$$\delta_{\text{total}} = \delta_{\text{rock}} + \delta_{\text{system}}$$

where

$$\delta_{\text{system}} = \delta_{\text{interface}} + \delta_{\text{loading platens}}$$

and δ_{rock} is the axial deformation of the whole rock specimen. Assume that the system deformation is proportional to the applied axial force F_a in the loading chain, i.e.

(1)

$$\delta_{\text{system}} = F_a / K_{\text{system}} \tag{2}$$

where K_{system} is the axial stiffness in the system (containing the interface between the rock and loading platens and the deformation of the loading platens). Combining (1) and (2) leads to

$$\delta_{\rm rock} = \delta_{\rm total} - F_{\rm a}/K_{\rm system} \tag{3}$$

where an expression of the axial deformation in the whole specimen is obtained. This can be viewed as a correction of the measurements made by system (S2). By using δ_{rock} to represent the axial deformation of the specimen that is based on a correction of the results of the total axial deformation will yield good results both in the loading range up to failure and at loading after failure. However, it is noticed that K_{system} is not known and has to be determined.

It was previously suggested that the local axial deformation measurement (S1) represents the real rock deformation well up to the load where the macro-cracks form. Further, it is fair to assume that the axial deformation is homogenous at this part of the loading. Hence, we get

$$\delta_{\rm rock} = \delta_{\rm local} \cdot L_{\rm total} / L_{\rm local} \tag{4}$$

This yields representative values of the total rock deformation for the first part of the loading up to the point where macro-cracking is taking place. It is now possible to determine δ_{system} up to the threshold of macro-cracking by combining (1) and (4) which yields

$$\delta_{\text{system}} = \delta_{\text{total}} - \delta_{\text{local}} \cdot L_{\text{total}} / L_{\text{local}}$$
(5)

Finally, we need to compute K_{system} . By rewriting (2) we get

$$K_{\rm system} = \frac{F_{\rm a}}{\delta_{\rm system}}$$

We will compute the system stiffness based on the results between 40% and 60% of the axial peak stress σ_{c} . This means that the Young's modulus and the Poisson ratio will take the same values both when the data from the local axial deformation measurement (S1) and when the data from corrected total axial deformation are used. Thus, we have

$$K_{\text{system}} = \frac{F_{a}(0.60\,\sigma_{c}) - F_{a}(0.40\,\sigma_{c})}{\delta_{\text{system}}(0.60\,\sigma_{c}) - \delta_{\text{system}}(0.40\,\sigma_{c})} \tag{6}$$

The results based on the correction according to (3) and (6) are presented in Section 5.1, whereas the original measured unprocessed data are reported in Appendix B.

A closure of present micro-cracks will take place initially during axial loading. Development of new micro-cracks will start when the load is further increased and axial stress reaches the crack initiation stress σ_i . The crack growth at this stage is as stable as increased loading is required for further cracking. A transition from a development of micro-cracks to macro-cracks will occur when the axial load is further increased. At a certain stress level the crack growth becomes unstable. The stress level when this happens is denoted the crack damage stress σ_d , cf /2/. In order to determine the stress levels, we look at the volumetric strain.

By subtracting the elastic volumetric strain \mathcal{E}_{vol}^{e} from the total volumetric strain, a volumetric strain corresponding to the crack volume \mathcal{E}_{vol}^{cr} is obtained. This has been denoted calculated crack volumetric strain in the literature, cf /2, 3/. We thus have

$$\varepsilon_{\rm vol}^{\rm cr} = \varepsilon_{\rm vol} - \varepsilon_{\rm vo}^{\rm e}$$

Assuming linear elasticity leads to

$$\varepsilon_{\rm vol}^{\rm cr} = \varepsilon_{\rm vol} - \frac{1 - 2\nu}{E} \sigma_{\rm a}$$

where $\sigma_r = 0$ was used. Experimental investigations have shown that the crack initiation stress σ_i coincides with the onset of increase of the calculated crack volume, cf /2, 3/. The same investigations also indicate that the crack damage stress σ_d can be defined as the axial stress at which the total volume starts to increase, i.e. when a dilatant behaviour is observed.

4.6 Nonconformities

The testing was conducted according to the method description with some deviations. The circumferential strains have been determined within a relative error of 1.5%, which is larger than what is specified in the ISRM-standard /1/. Further, double systems for measuring the axial deformation have been used, which is beyond the specifications in the method description. This was conducted as development of the test method specially aimed for high-strength brittle rock.

Specimen KLX05A-113-1 was replaced by specimen KLX05A-113-5, specimen KLX05A-113-6 was replaced by specimen KLX05A-113-10 and specimen KLX05A-113-18 was replaced by specimen KLX05A-113-19. Except for this, the activity plan was followed with no departures.

5 Results

The results of the individual specimens are presented in Section 5.1 and a summary of the results is given in Section 5.2. The reported parameters are based both on unprocessed raw data obtained from the testing and processed data and were reported to the SICADA database, where they are traceable by the activity plan number. These data together with the digital photographs of the individual specimens were handed over to SKB. The handling of the results follows SDP-508 (SKB internal controlling document) in general.

5.1 Results for each individual specimen

The cracking is shown in photos of the specimens, and comments on observations made during the testing are reported. The elasticity parameters have been evaluated by using the results from the local axial deformation measurements. The data from the adjusted total axial deformation measurements, cf Section 4.4, are shown in this section. Red rings are superposed on the graphs indicating every five minutes of the progress of testing.

Diagrams showing the data from both the local and the total axial deformation measurements, system (S1) and (S2) in Figure 3-3, and the computed individual values of K_{system} used at the data corrections are shown in Appendix B. Diagrams displaying actual radial strain rates versus the test time are also presented in Appendix B. The results for the individual specimens are as follows:

Before mechanical test

After mechanical test

 Diameter (mm)
 Height (mm)
 Density (kg/m³)

 50.1
 127.6
 2,810

Comments:

Spalling along one side of the specimen is observed.

Youngs Modulus (E):	69.9	[GPa]
Poisson Ratio (v):	0.326	[–]
Axial peak stress (σ_c):	186.6	[MPa]

Before mechanical test

After mechanical test

 Diameter (mm)
 Height (mm)
 Density (kg/m³)

 50.1
 128.2
 2,810

Comments:

Spalling along one side of the specimen is observed.

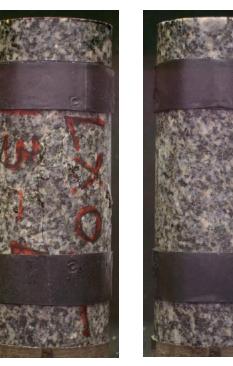

Youngs Modulus (E):	69.4	[GPa]
Poisson Ratio (v):	0.293	[–]
Axial peak stress (σ_c):	185.6	[MPa]

Before mechanical test

After mechanical test

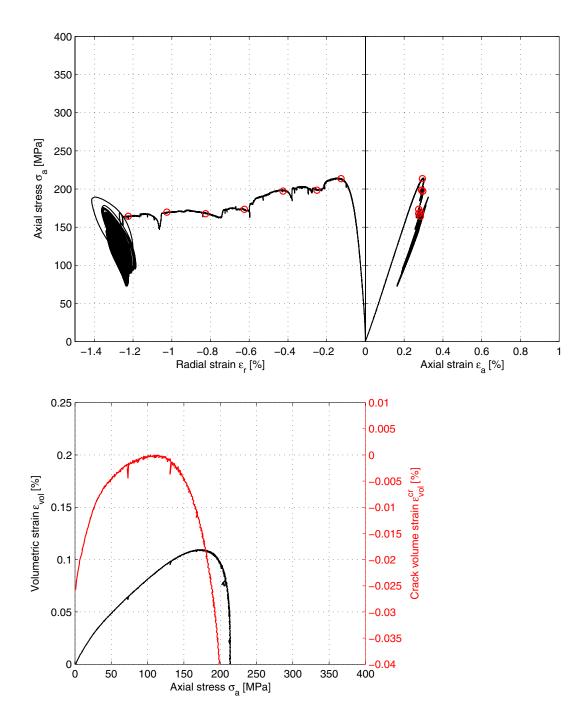

Diameter (mm) Height (mm) Density (kg/m³) 49.9 127.7

2,800

Comments:

Spalling along one side of the specimen is observed. The specimen fractured and the load started to oscillate when the radial strain had reached -1.2% and the test was stopped.

Youngs Modulus (E):	77.9	[GPa]
Poisson Ratio (v):	0.279	[–]
Axial peak stress (σ_c):	214.3	[MPa]

Before mechanical test

After mechanical test

 Diameter (mm)
 Height (mm)
 Density (kg/m³)

 49.9
 127.7
 2,800

Comments:

Spalling along one side of the specimen is observed. The specimen fractured and the load started to oscillate when the radial strain had reached -0.9% and the test was stopped.

Youngs Modulus (E):	75.4	[GPa]
Poisson Ratio (v):	0.254	[–]
Axial peak stress (σ_c):	209.1	[MPa]

Before mechanical test

After mechanical test

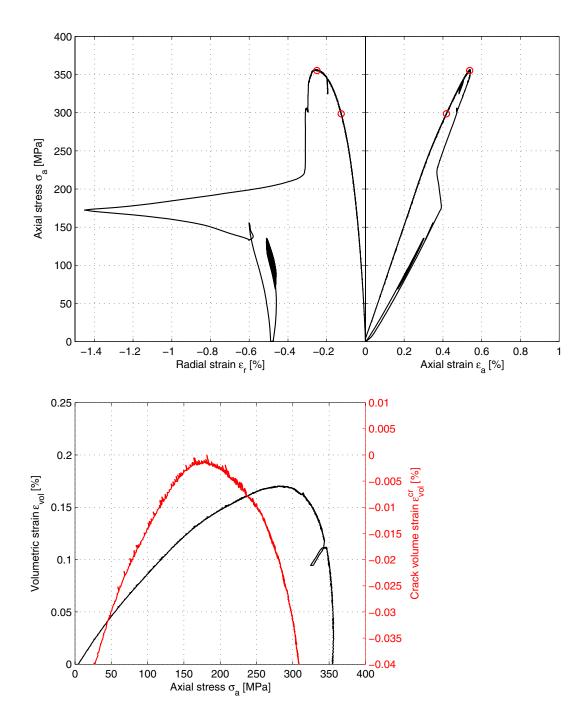

Diameter (mm)	Height (mm)	Density (kg/m³)
50.0	126.6	2,660

Comments:

Deep spalling along one side of the specimen is observed. A sudden change of the radial strain due to fracturing occurred when the radial strain had reached -0.3%. This caused a complete unloading of the specimen. The test was restarted, but the load started to oscillate almost immediately and the test was stopped.

Youngs Modulus (E):	74.7	[GPa]
Poisson Ratio (v):	0.315	[-]
Axial peak stress (σ_c):	356.4	[MPa]

Comments:

Spalling along one side of the specimen is observed.

Youngs Modulus (E):	74.2	[GPa]
Poisson Ratio (v):	0.274	[–]
Axial peak stress (σ_c):	273.7	[MPa]

Before mechanical test

After mechanical test

 Diameter (mm)
 Height (mm)
 Density (kg/m³)

 50.0
 128.6
 2,650

Comments:

Spalling along one side of the specimen is observed. The specimen fractured and the load started to oscillate for a short time when the radial strain had reached -0.2% but was stabilized. The test proceeded and the load started to oscillate once again when the radial strain had reached -0.5% and the test was stopped.

Youngs Modulus (E):	72.3	[GPa]
Poisson Ratio (v):	0.279	[–]
Axial peak stress (σ_c):	279.8	[MPa]

Before mechanical test

After mechanical test

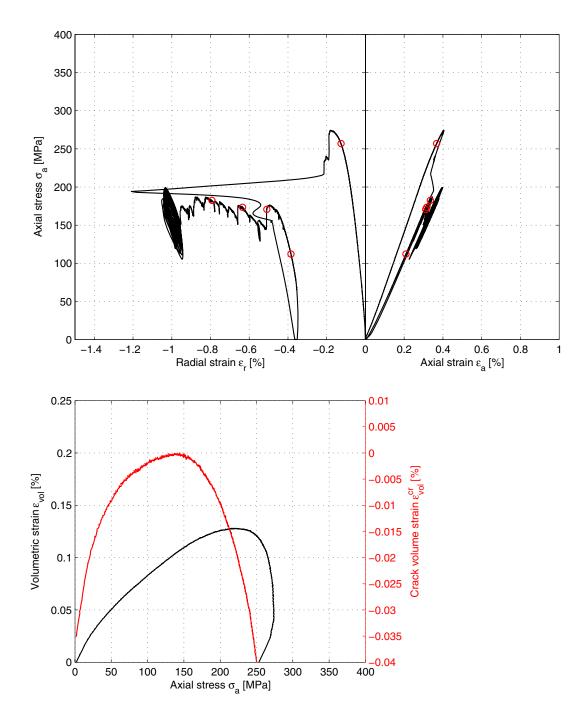

Diameter (mm)	Height (mm)	Density (kg/m³)
50.1	128.6	2,660

Comments:

Deep spalling along one side of the specimen is observed. A sudden change of the radial strain due to fracturing occurred when the radial strain had reached -0.2%. This caused a complete unloading of the specimen. The test was restarted and the load started to oscillate when the radial strain had reached -1.0% and the test was stopped.

Youngs Modulus (E):	72.5	[GPa]
Poisson Ratio (v):	0.316	[–]
Axial peak stress (σ_c):	274.2	[MPa]

Before mechanical test

After mechanical test

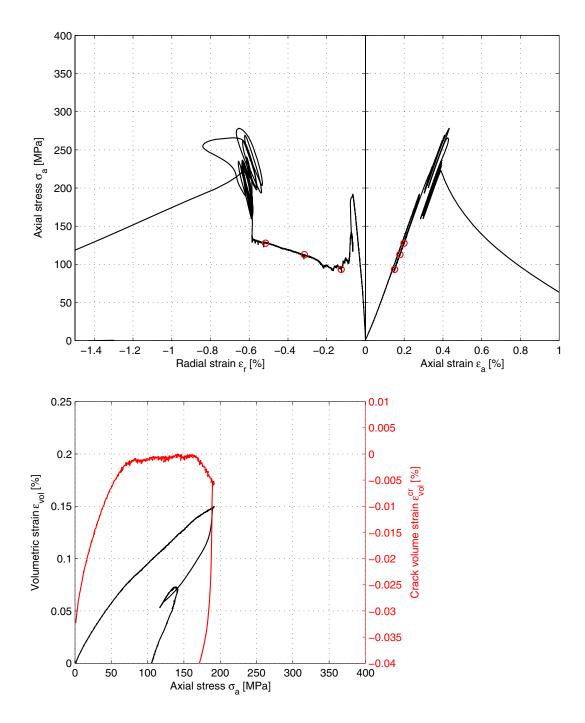

Diameter (mm)	Height (mm)	Density (kg/m³)
50.1	128.8	2,660

Comments:

Almost vertical fracturing of the specimen following material foliations together with shallow spalling are observed. The specimen began to fracture when the axial stress was about 180 MPa resulting in some unloading. The test proceeded with a continuous reloading of the specimen at a low rate. When the radial strain had reached -0.6 % the load began to increase with approximately the same rate as the initial one. The maximum axial stress was reach at this stage. The load started to oscillate and the test was stopped.

Youngs Modulus (E):	70.6	[GPa]
Poisson Ratio (v):	0.272	[–]
Axial peak stress (σ_c):	278.1	[MPa]

Appendix A

The following equations describe the calculation of radial strains when using a circumferential deformation device, see Figure A-1.

$$\varepsilon_{\rm r} = \frac{\Delta C}{C_{\rm i}}$$

where

 $C_i = 2 \pi R_i$ = initial specimen circumference

and

$$\Delta C = \text{change in specimen circumference} = \frac{\pi \cdot \Delta X}{\sin\left(\frac{\theta_i}{2}\right) + \left(\pi - \frac{\theta_i}{2}\right)\cos\left(\frac{\theta_i}{2}\right)}$$
and

 ΔX = change in LVDT reading = $X_{\rm i} - X_{\rm f}$

 $(X_i = initial chain gap; X_f = current chain gap)$

$$\theta_{i} = \text{initial chord angle} = 2\pi - \frac{L_{c}}{R_{i} + r}$$

 $L_{\rm c}$ = chain length (measured from center of one end roller to center of the other end roller)

r = roller radius

 $R_{\rm i}$ = initial specimen radius

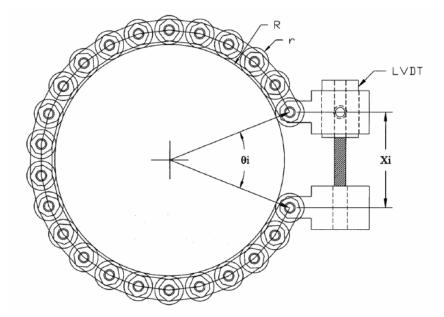

Figure A-1. Chain for radial deformation measurement.

This Appendix contains results showing the unprocessed data and values on the computed system stiffness K_{system} that was used for the data processing, cf Section 4.4. In addition graphs showing the volumetric strain ε_{vol} versus the axial strain ε_{a} and the actual radial strain rate $d\varepsilon_{r}/dt$ versus time are also displayed.
