## **Abstract**

This report includes the data gained during geophysical logging operations performed within the site investigation at Forsmark. The logging operations presented here include borehole radar (RAMAC) and BIPS in the core drilled borehole KFM05A. All measurements were conducted by Malå Geoscience AB / RAYCON during May and June 2004.

The objective of the radar survey is to achieve information on the rock mass around the borehole. Borehole radar and BIPS are used to investigate the nature and the structure of the rock mass enclosing the boreholes.

The borehole radar data quality from KFM05A was good, but in some parts of lower quality due to more conductive conditions. This electrically conductive environment reduces the possibility to distinguish and interpret possible structures in the rock mass. The borehole radar measurements resulted in a number of identified radar reflectors. In KFM05A almost 200 radar reflectors were identified and half of them also orientated (strike/dip).

Four runs with the BIPS were performed. The first logging was made to inspect a fracture zone that had been noted at a depth of 109 metre during the drilling operation. After evaluating the result from the BIPS survey it was decided to extend the casing down to 110 metre. The second logging produced images of bad quality and was discontinued and so was the third one. The final logging was carried out 2004-06-03 from 110 metre down to 995 metre and revealed almost perfect water quality. This logging produced high quality images for the core logging.

## **Sammanfattning**

Denna rapport omfattar geofysiska loggningar inom platsundersökningsprogrammet för Forsmakr. Mätningarna som presenteras här omfattar borrhålsradar- och BIPS-mätningar i kärnborrhål KFM05A. Alla mätningar är utförda av Malå Geoscience AB /RAYCON under maj och juni 2003.

Syftet med radarmätningarna och BIPS är att samla information om bergmassan runt borrhålet. Borrhålsradar och BIPS används till att karakterisera bergets egenskaper och strukturer i bergmassan närmast borrhålet.

Borrhålsradardata från KFM05A var bra, men tidvis av sämre kvalité troligen till stor del beroende på en konduktiv miljö. En elektriskt konduktiv miljö minskar möjligheterna att identifiera strukturer ur borrhålsradardata. Nästan 200 radarreflektorar identifierades i KFM05A, varav ungefär hälften har kunnat orienteras (strykning/stupning).

BIPS-loggning har utförts vid fyra tillfällen. Den första loggningen gjordes för att studera en sprickzon som noterats på 109 m djup under pågående borrning. Efter utvärdering av BIPS-bilderna togs beslut om att sätta foderrör ned till 110 m. Vid loggningstillfällena två och tre avbröts mätningarna på grund att bildernas kvalitet blev dålig. Vid det fjärde loggningstillfället producerades bilder av hög kvalitet för borrkärnekarteringen.

# 1 Introduction

This document reports data gained during geophysical logging operations, which is one of the activities performed within the site investigation at Forsmark. The logging operations presented here include borehole radar (RAMAC) and TV-logging (BIPS) and was carried out in the core drilled borehole KFM05A, see Table 1-1 and Figure 1-1.

The measurements in KFM05A were made from 110 m to a depth of approximately 1,000 m.

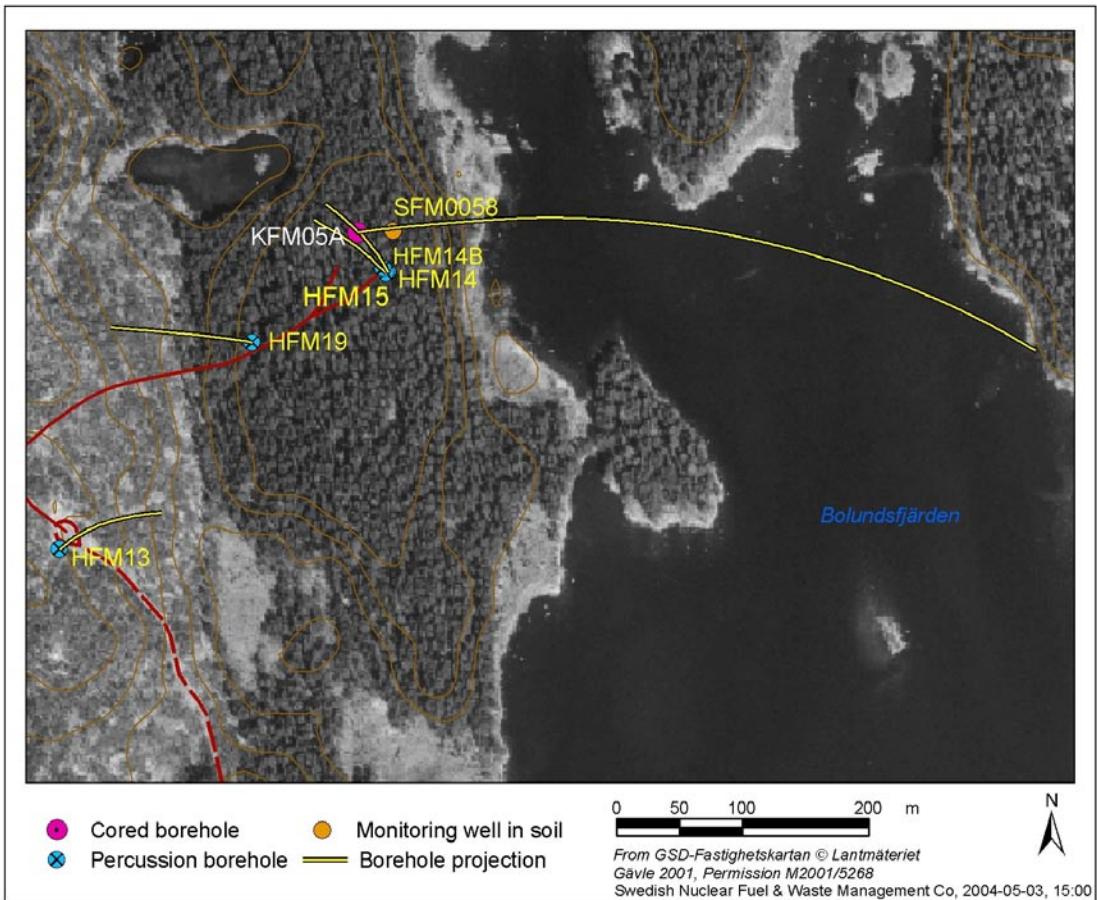

The borehole radar and BIPS measurements were conducted by Malå Geoscience AB/RAYCON during May and June 2004, according to Activity Plan AP 400-04-47 (SKB internal controlling document).

The applied investigation techniques comprised:

- Borehole radar with both dipole and directional radar antennas.
- Borehole TV logging with the so-called BIP-system (Borehole Image Processing System), which is a high resolution, side viewing, colour borehole TV system.

**Table 1-1. Investigated borehole.**

**Figure 1-1.** Overview of boreholes at drill site no 5 in the Forsmark area.

## **2     Objective and scope**

The objective of the radar- and BIPS-surveys was to achieve information on the borehole conditions (borehole wall) as well as on the rock mass around the borehole. Borehole radar was engaged to investigate the nature and the structure of the rock mass enclosing the boreholes, and borehole TV for geological surveying of the borehole including determination of fracture distribution and orientation.

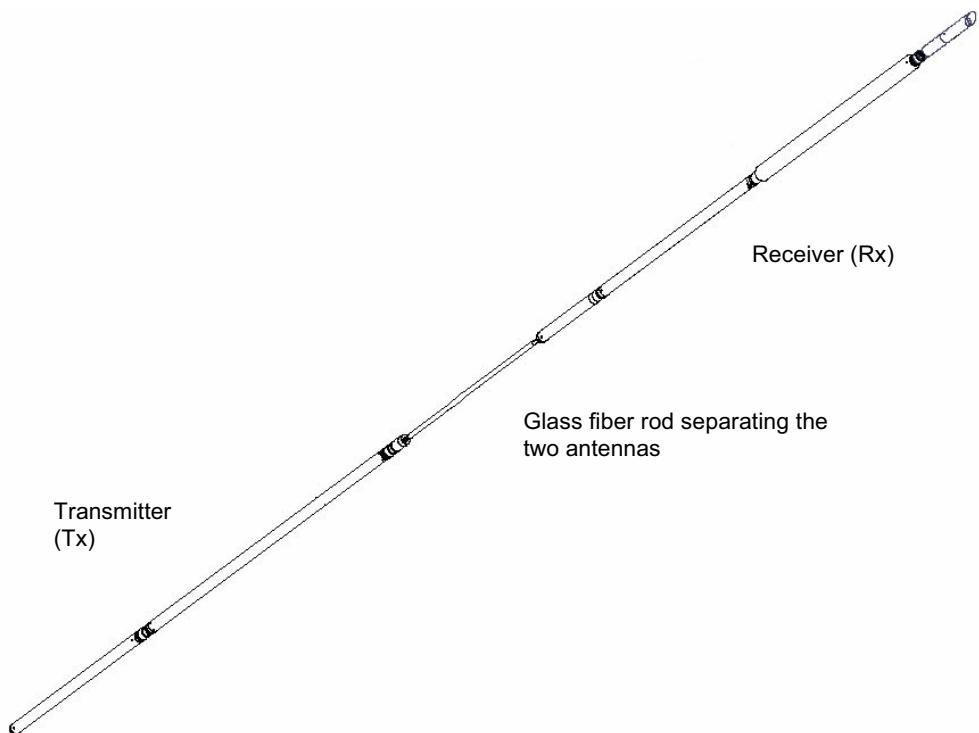

This report describes the equipment used as well the measurement procedures and data gained. For the BIPS-survey, the result is presented as images. Radar data is presented in radargrams and the identified reflectors are listed.

## 3 Equipment

### 3.1 RAMAC

The RAMAC GPR system owned by SKB is a fully digital, and emphasis has been laid on high survey speed and smooth field operation. The system operates dipole and directional antennas (see Figure 3-1). A system description is given in the method description “Metodbeskrivning för borrhålsradar” (SKB MD 252.020, Version 1.0).

The borehole radar system consists of a transmitter and a receiver. During operation an electromagnetic pulse, within the frequency ranges 20 to 250 MHz, is emitted and penetrates the bedrock. The resolution and penetration of the radar waves depend on the antenna frequency used. A low antenna frequency results in lower resolution but higher penetration rate compared to a higher frequency. If a feature, e.g. a water-filled fracture, with anomalous electrical properties compared to the surrounding is encountered, the pulse is reflected back to the receiver and recorded.

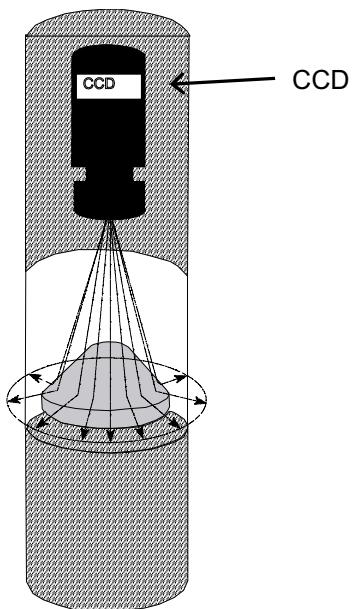

*Figure 3-1. Example of a borehole antenna.*

### 3.2 TV-Camera, BIPS

The BIPS 1500 system used is owned by SKB and described in the method description “Metodbeskrivning för TV-loggning med BIPS” (SKB MD 222.006, Version 1.0). The BIPS method for borehole logging produces a digital scan of the borehole wall. In principle, a standard CCD video camera is installed in the probe in front of a conical mirror (see Figure 3-2). An acrylic window covers the mirror part and the borehole image is reflected through the window and displayed on the cone, from where it is recorded. During the measuring operation, pixel circles are grabbed with a resolution of 360 pixels/circle.

The system orients the BIPS images according to two alternative methods, either using a compass (vertical boreholes) or with a gravity sensor (inclined boreholes).

**Figure 3-2.** The BIP-system. Illustration of the conical mirror scanning.

## 4 Execution

### 4.1 Data aquisition

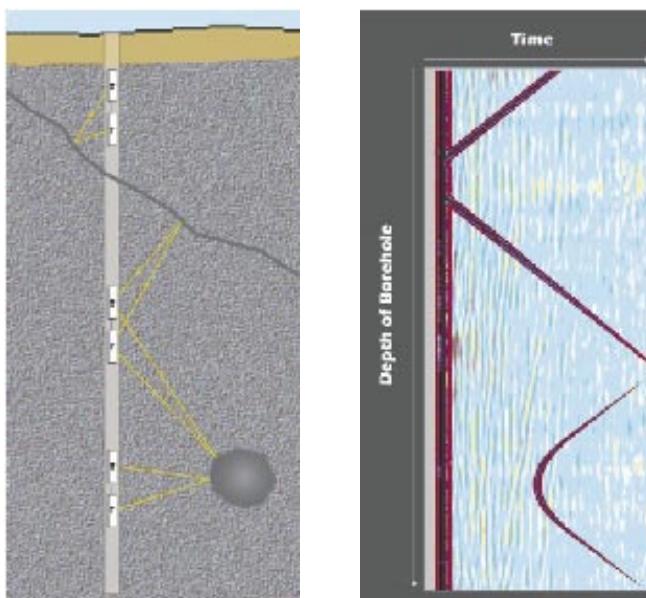

#### RAMAC

For the borehole radar measurements, both dipole and directional antennas were engaged. The dipole antennas used have central frequencies of 20 MHz, 100 MHz and 250 MHz respectively, whereas the directional antenna has a central frequency of 60 MHz.

During logging, the dipole antennas (transmitter and receiver) were lowered continuously into the borehole and the data recorded on the field PC. The measurements with the directional antenna were made step-wise, with a short pause for each measurement. The antennas (both dipole and directional) are kept at a fixed separation by glass fibre rods according to Table 4-1. See also Figure 3-1 and 4-1.

For detailed information, see the SKB MD 252.020 for method description and MD 600.004 for cleaning of equipment.

Information on the system settings for the different antennas used in the investigation of KFM05A is presented in Table 4-1.

## BIPS

For detailed information on BIPS measurements, see the SKB MD 222.006 for a method description and MD 600.004 for cleaning of equipment.

During the measurement, a pixel circle with a resolution of 360 pixels/circle was used and the digital circles were stored at every 1 mm on a MO-disc in the surface unit. The maximum speed during data collection was 1.5 m/minute.

A gravity sensor was used to measure the orientation of the BIPS images.

## Depth measurements

The depth recording for the RAMAC and BIPS systems is taken care of by a measuring wheel mounted on the cable winch. Whenever reference marks in the borehole are visible on the image displayed by the ground unit during the BIPS logging, the logging cable is marked with a piece of scotch tape. These marks are then used for controlling the depth registration during the RAMAC measurements.

The depth divergence in KFM05A is less than 10 cm in the deepest parts of the borehole.

## 4.2 Analyses and interpretation

### Radar

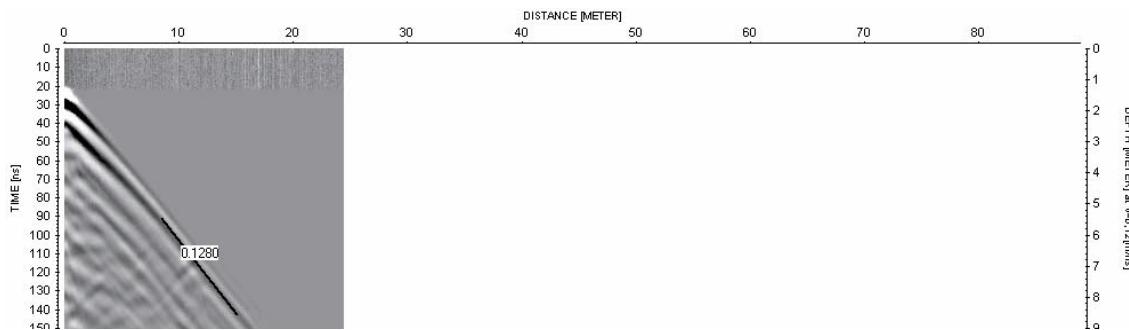

The results from radar measurements are commonly presented in the form of a radargram where the position of the probes is displayed along one axis and the propagation along the other. The amplitude of the received signal is shown with a grey scale where black colour corresponds to the large positive signals and white colour to large negative signals. Grey colour corresponds to no reflected signals.

The data presented in this report is related to the “measurement point”, which is defined to be the centre between the transmitter and the receiver antenna.

In the reflection mode, borehole radar primarily offer a high-resolution image of the rock mass, visualizing the geometry of plane structures (contacts between rock units of different lithology, thin marker beds, fractures, fracture zones etc), which may or may not intersect the borehole, or showing the presence of local features (cavities, lenses etc) around the borehole.

The distance to a reflecting object or plane is determined by measuring the difference in arrival time between the direct and the reflected pulse. The basic assumption is that the speed of propagation is consistent in the rock volume investigated.

There are several ways to determine the radar wave propagation velocity. Each of them has its advantages and its disadvantages. In this project, the velocity determination was performed by keeping the transmitter fixed in a borehole at drill site no 1 (the percussion drilled borehole HFM03) while moving the receiver downwards in the borehole. The result is plotted in Figure 4-3. The calculation shows a velocity of 128 m/micro seconds. The velocity measurement was performed with the 100 MHz antenna /1/.

*Figure 4-2. Results from velocity measurements in HFM03 /1/.*

The visualization of data in Appendix 1 and 2 is made with REFLEX, a Windows based processing software for filtering and analysis of radar data. The processing steps are shown in Table 4-2.

For the interpretation of the intersection angle between the borehole axis and the planes visible on the radargrams the RadinterSKB software has been applied. RadinterSKB is also used to interpret the orientation of structures identified in the data obtained by the directional antenna. The interpreted intersection points and intersection angles of the detected structures are presented in the Table 5-2 and also visible on the radargrams in Appendix 1 and 2.

### **BIPS**

The visualization of data (see Appendix 3) is made with BDPP, a Windows based processing software for filtering, presentation and analyzing of BIPS data. No fracture mapping of the BIPS image was performed.

## **5 Results and data delivery**

The results from the radar and BIPS measurements were delivered as raw data (\*.bip-files) on CD-ROMs to SKB together with printable BIPS pictures in \*.pdf format before the field crew left the investigation site. The information of the measurements is registered in SICADA, and the CD-ROMs stored by SKB.

RAMAC radar data have been delivered as raw data (fileformat \*.rd3 or \*.rd5) with corresponding information files (file format \*.rad), whereas the data processing steps and results are presented in this report. Relevant information, including the interpretation presented in this report, has been inserted into the SKB database SICADA.

The SICADA reference to the BIPS and RAMAC logging activity in KFM05A is field note Forsmark no 289 and 319.

### **5.1 RAMAC logging**

The functionality of the directional antenna was tested before the measurements were carried out. This was done by measuring in the air. While measuring, the receiver antenna is turned and this way the direction to the transmitter antenna is determined. The difference in direction measured by compass and the result achieved from the directional antenna was about 10 degrees. This is considered to be satisfying, taking into account the somewhat disturbed environment at the site.

The results of the interpretation of the radar measurements are presented in Table 5-1 and 5-2. Radar data for the dipole antennas are also visualized in Appendix 1 and 2. It should be remembered that the images in Appendix 1 and 2 are only composite pictures of all events, 360 degrees around the borehole, and do not reflect the true orientation of the structures. Results from measurements with the directional antenna are only shown in tabulated form, Table 5-2, with the identified planes and their orientation.

Only the major, clearly visible structures are interpreted in RadinterSKB. A number of minor structures were also encountered as indicated in Appendix 1 and 2.

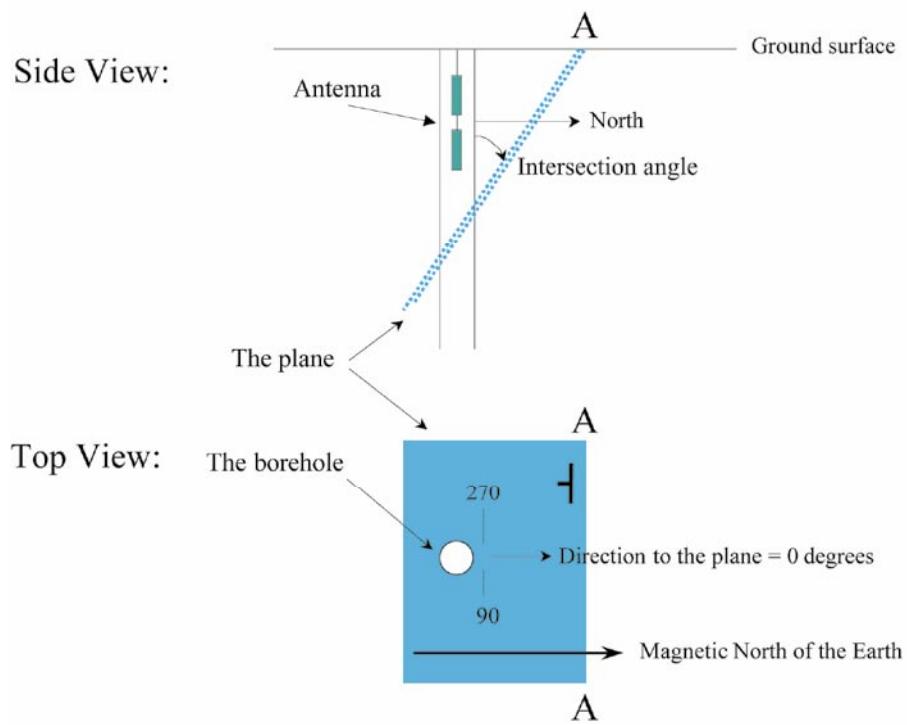

The data quality is good. However, measurements in minor parts of the borehole suffer from deteriorated quality due to increased electrical conductivity in the rock or borehole fluid. A conductive environment entails attenuation of the radar waves, resulting in decreased penetration.

As also seen in Appendix 1 and 2, the resolution and penetration of the radar waves depend of the antenna frequency. A high frequency will result in a high resolution but a lower penetration rate compared to a lower frequency.

**Table 5-1. Identified structures as a function of depth in KFM05A.**

| Depth (m) | No of structures | Depth (m) | No of structures |
|-----------|------------------|-----------|------------------|
| 0–150     | 14               | 550–600   | 9                |
| 150–200   | 13               | 600–650   | 16               |

| 250–300   | 11               | 700–750   | 12               |
| 300–350   | 7                | 750–800   | 7                |
| 350–400   | 15               | 800–850   | 5                |
| 400–450   | 14               | 850–900   | 4                |
| 450–500   | 10               | 900–950   | 11               |
| 500–550   | 11               | 950–      | 17               |

Table 5-2 summarises the interpretation of radar data from KFM05A. Many structures can be identified in the data from more than one antenna frequency. When an object (in this case plane) is detected by the directional antenna, the direction to the plane, as defined in Figure 5-1, is interpreted. Based on this information, the true orientation (strike and dip) of the plane can be calculated, see Table 5-2. In some cases, however, there is an uncertainty ( $\pm 180$  degrees) in the interpretation of the direction to the plane. Object direction 1, strike 1 and dip 1 in Table 5-2 then represent the most probable interpretation.

**Figure 5-1. Definition of the direction to object as presented in Table 5-2.**

**Table 5-2. Model information from dipole antennas 20, 100 and 250 MHz and the directional, 60 MHz antenna. See Figure 5-1 for definition of properties.**

Names in table according to Appendix 1 and 2.

In Appendix 1, the amplitude of the first arrival is plotted against the depth, for the 250 MHz dipole antennas. The amplitude variation along the borehole indicates changes of the electrical conductivity of the material. A decrease in this amplitude may indicate fracture zones, clay or rock volumes with increases water content. The decrease in amplitude is seen for the following sections in KFM05A:

| Depth (m) |         |         |         |         |         |     |
|-----------|---------|---------|---------|---------|---------|-----|
| 110–115   | 205–215 | 405     | 475–480 | 595     | 705     | 840 |
| 150       | 360–360 | 415–425 | 495     | 610–615 | 715–725 | 905 |
| 165       | 375     | 425–430 | 505     | 625–630 | 755     | 980 |
| 185       | 395     | 445     | 540     | 670–675 | 795     |     |

## 5.2 BIPS logging

In order to control the quality of the BIP system, calibration measurements were performed in a test pipe before and after logging of the borehole. The resulting images displayed no difference regarding the colours and focus of the images. Results of the test loggings were included in the delivery of the raw data.

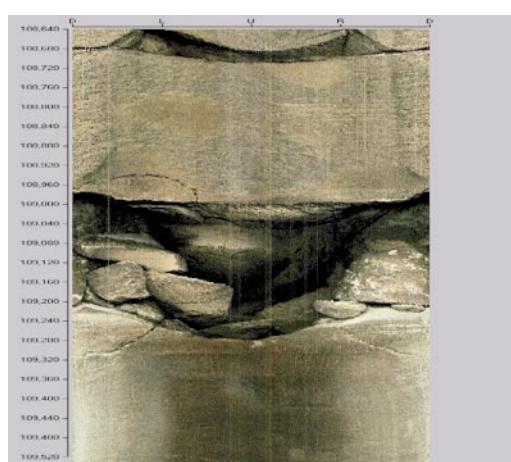

To get the best possible depth accuracy, the BIPS images are adjusted (red figures in Appendix 3) to the reference marks along the borehole.

Four runs with the BIPS were performed in the borehole. The aim of the first logging 2004-04-21 was to inspect a fracture zone that had been noted at a depth of 109 metre during the drilling operation. The concern was if loose rock pieces in the borehole wall could fall in to the borehole and cause jamming. After evaluating the result from the BIPS survey it was decided to extend the casing down to 110 metre. Figure 5-2 shows the BIPS image of the zone before it was cased.

The second logging 2004-05-08 indicated quite bad water quality and was therefore discontinued at 251 metre. The third logging 2004-05-10 showed an improved visibility but still the bottom part was covered with a thin layer of mud. The logging was discontinued at a depth of 500 metre. Images from these two loggings are not presented in this report.

The last BIPS logging was carried out 2004-06-03 from 110 metre down to 995 metre and revealed almost perfect water quality, see Appendix 3. The improvement of the water quality, a couple of weeks after the finish of the drilling has been observed in several boreholes from both the Forsmark and Oskarshamn sites. Discolouring of some parts of the borehole due to the drilling is however still seen.

To sum up, the BIPS logging has produced high quality images for the core logging.

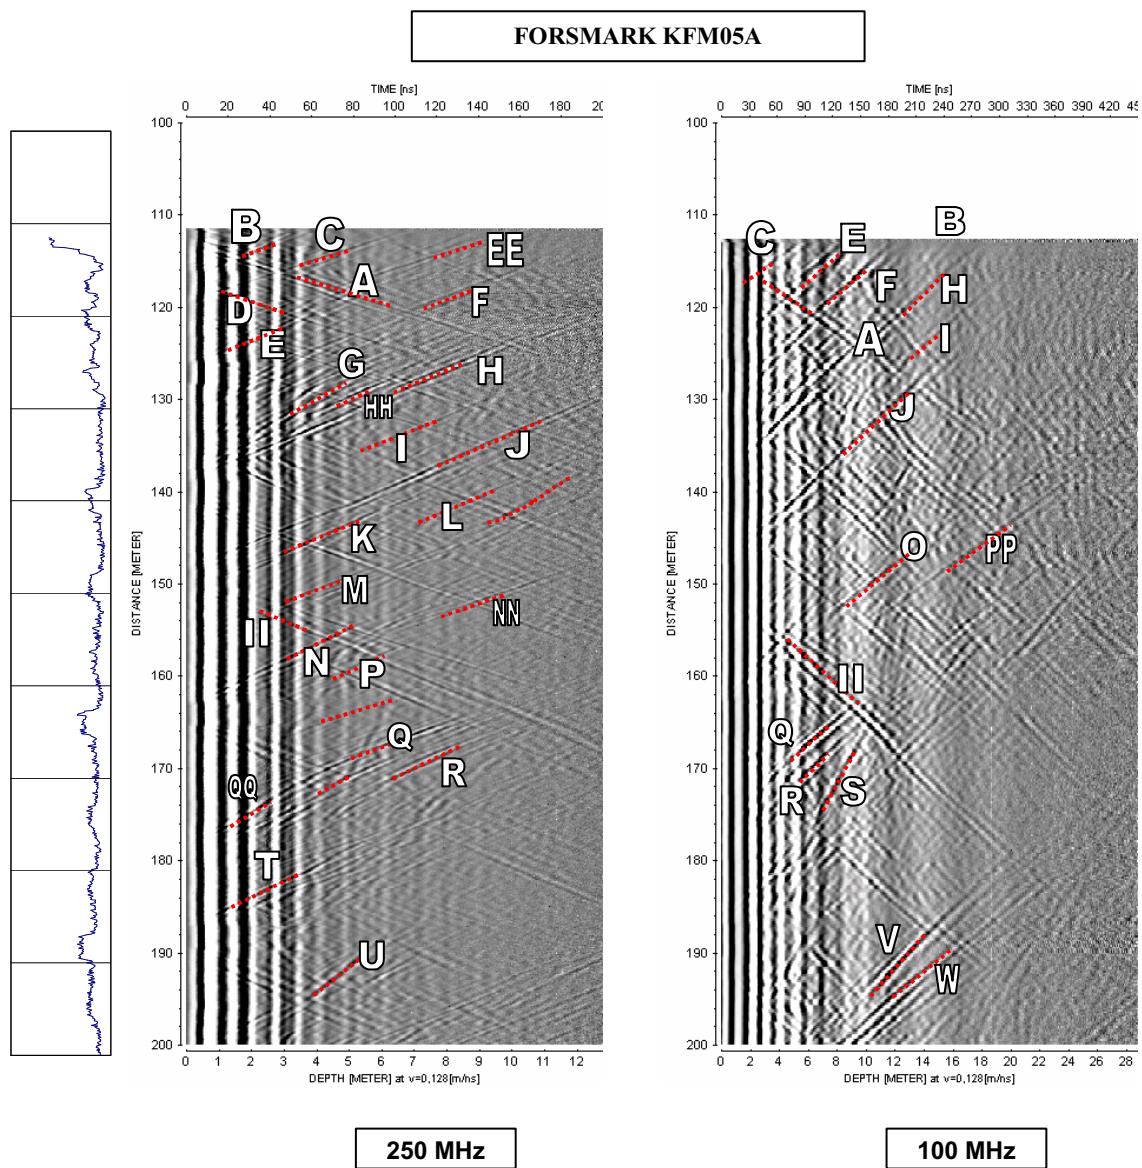

**Figure 5-2.** BIPS image of the fracture zone at 109 metre.
