This report concerns a study which was conducted for SKB. The conclusions and viewpoints presented in the report are those of the authors and do not necessarily coincide with those of the client.

Data in SKB's database can be changed for different reasons. Minor changes in SKB's database will not necessarily result in a revised report. Data revisions may also be presented as supplements, available at [www\(skb.se\)](http://www(skb.se)).

A pdf version of this document can be downloaded from [www\(skb.se\)](http://www(skb.se)).

Abstract

This report presents the result from the Boremap mapping of core drilled borehole KFM08D at drill site 8 in the Forsmark candidate area. Drill site 8 (DS 8) is situated in the north-eastern part of the candidate area. The borehole was drilled with the bearing 100.0°, inclination –55.0° and a core was recovered from 60.80 to 941.76 m. The aims of the drilling were to receive geological data of the rock volume in the north-eastern part of the candidate area, and to verify the existence and obtain properties of north-northeast trending deformation zones.

The dominant rock type in KFM08D is a generally foliated metagranite-granodiorite (~ 78%) followed by fine- to medium-grained metagranitoid (~ 9%) and pegmatitic granite (~ 5%). Subordinate rock types comprise medium-grained metadiorit-gabbro (3%), amphibolite (~ 3%), fine- to medium-grained granite (~ 2%), felsic to intermediate metavolcanic rock (< 1%) and aplitic metagranite (< 1%). The section mapped without BIPS-image is not included.

The borehole shows fracture frequencies of 1.5 open and partly open fractures/m and 5.9 sealed fractures/m. The sections mapped without BIPS-image are not included.

Borehole sections with increased fracture frequencies with open fractures, sealed fractures and sealed fracture networks are concentrated to the intervals 184–210 m, 544–570 m, 582–609 m, 621–688 m, 737–570 m, 819–842 m and 900–941.76 m. The borehole intervals 184–210 m, 582–609 m and 621–688 m also includes fractures with apertures ranging up to 10 mm. The most frequent fracture minerals are chlorite, calcite, clay minerals and adularia.

Two intervals with generally medium to strong albitization occur at 395–580 m and 610–840 m borehole length. These intervals also include sections with faint to medium intensity of oxidation.

Sammanfattning

Denna rapport redovisar resultatet från Boremapkartering av kärnborrhålet KFM08D vid borrplats 8 i Forsmark kandidatområde. Borrplats 8 är belägen i den nordligaste delen av en tektonisk lins, som har utvalts att vara kandidatområde för deponering av kärnavfall. Borrhålet är borrat med riktning 100° , lutning -55.0° . Borrkärna finns för sektionen mellan 60,80 och 941,76 m. Syftet med borrningen var att erhålla geologiska data för bergvolymen i den nordöstra delen av kandidatområdet, och att belägga förekomst och egenskaper för nord-nordostliga deformationszoner i området.

Den dominerande bergarten i KFM08D är en generellt folierad metagranit-granodiorit ($\sim 78\%$), följd av fin- till medelkornig granit ($\sim 9\%$) och pegmatit till pegmatitisk granit ($\sim 5\%$). Underordnade bergarter är medelkornig metadiorit-gabbro ($\sim 3\%$), amfibolit ($\sim 3\%$), fin- till medelkornig metagranitoid ($\sim 2\%$), fin- till medelkornig granit ($\sim 1\%$), felsisk till intermediär metavulkanit ($< 1\%$) och aplitisk metagranit ($< 1\%$). Sektionen karterad utan BIPS-bild är inte inkluderad.

Borrhålet uppvisar sprickfrekvenser på 1,5 öppna och delvis öppna sprickor/m och 5,9 läkta sprickor/m. Sektionen karterad utan BIPS-bild är inte inkluderad.

Sektioner med ökad sprickfrekvens av öppna sprickor, läkta sprickor och läkta spricknätverk är koncentrerade i intervallen: 184–210 m, 544–570 m, 582–609 m, 621–688 m, 737–570 m, 819–842 m och 900–941,76 m. Inom borrhålsintervallen 184–210 m, 582–609 m och 621–688 m finns även sprickor med apertur upp till 10 mm. De vanligast förekommande sprickmineralen är klorit, kalcit, lermineral och adularia.

Två borrhålsintervall med generellt medium till stark albitisering förekommer mellan 395–580 m och 610–840 m. Dessa intervall inkluderar också sektioner med oxidation med svag till medelstark intensitet

1 Introduction

This document reports the data gained by the Boremap mapping of the core drilled borehole KFM08D, which is one of the activities performed within the site investigation at Forsmark. The work was carried out in accordance with activity plan AP PF 400-06-116. In Table 1-1 controlling documents for performing this activity are listed. Both activity plan and method descriptions are SKB's internal controlling documents.

The borehole KFM08D was drilled from drill site 8 (DS 8) in the northernmost part of the tectonic lens which is of interest for future nuclear waste disposal (Figure 2-1) /1/. The borehole was drilled in easterly direction, in order to document rock type distribution and NNE-trending deformation zones. The drilling of KFM08D was finished on February 6th 2007 /4/. The Boremap mapping of the borehole started on January 18th and was finished on March 28th 2007.

The geological documentation of core drilled boreholes according to the Boremap method is based on the use of BIPS-images of the borehole wall and the simultaneous study of the drill core. Position, aperture and orientation data of features are based on the adjusted BIPS-image, while other data such as rock type, alteration, fracture mineralogy and surface are observed in the drill core. The Boremap mapping will be used for further 3D-modelling in the Forsmark area.

Original data from the reported activity are stored in the primary database Sicada, where they are traceable by the Activity Plan number (AP PF 400-06-116). Only data in SKB's databases are accepted for further interpretation and modelling. The data presented in this report are regarded as copies of the original data. Data in the databases may be revised, if needed. Such revisions will not necessarily result in a revision of the P-report, although the normal procedure is that major data revisions entail a revision of the P-report. Minor data revisions are normally presented as supplements, available at www.skb.se.

2 Objective and scope

The aim of this activity was to document lithologies, alterations, ductile structures and the occurrence and character of fractures in the bedrock penetrated by the core drilled borehole KFM08D. The detailed documentation will be used in 3D-modelling of the area.

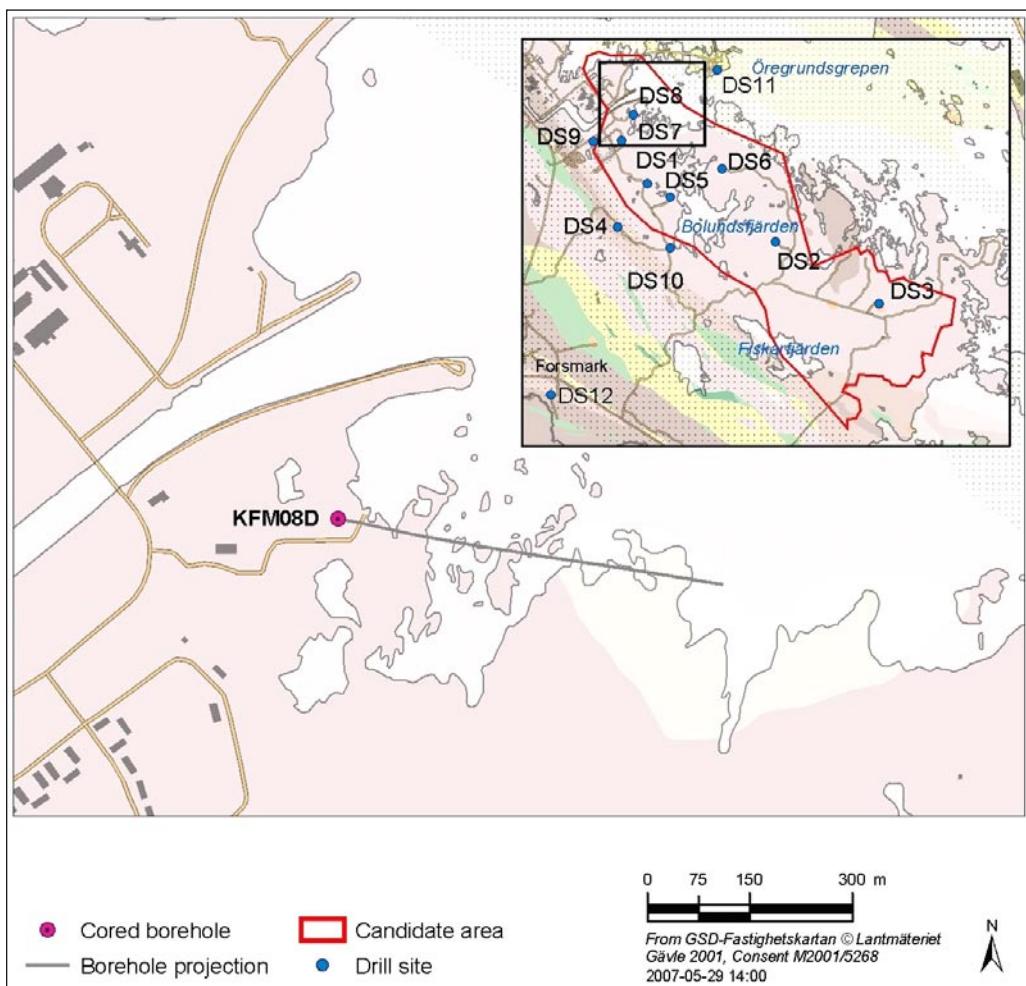

Figure 2-1. Location of borehole KFM08D.

3 Equipment

3.1 Description of equipment and interpretation tools

Mapping of BIPS-images and drill core was performed with the software Boremap v. 3.9.0.2 and v. 3.9.2.0. The Boremap software is loaded with the bedrock and mineral standard used for surface mapping at the Forsmark investigation site to enable correlation with the surface geology. The Boremap software calculates actual directions (strike and dip) of planar structures penetrated by the borehole (foliations, fractures, fracture zones, rock contacts etc). Data on inclination, bearing and diameter of the borehole are used as in-data for the calculations (Table 4-2, Appendix 2). The BIPS-image lengths were calibrated (Table 4-1).

Additional software used during mapping are BIPS Image Viewer and MicroSoft Access 2003. The schematic data presentation was made in WellCad v. 4.0.

The following equipment was used to facilitate the core documentation: folding rule, 10% hydrochloric acid, rock hardness tool, hand lens, paint brush and tap water.

3.1.1 BIPS-image quality

The following factors may disturb the mapping:

- 1) blackish coatings probably related to the drilling equipment,
- 2) vertical bleached bands from the drill cuttings in suspension,
- 3) light and dark bands at high angle to the borehole related to the automatic aperture of the video camera,
- 4) vertical enlargements of pixels due to stick-slip movement of the camera probe.

The BIPS-image of KFM08D suffers from blackish coatings from the drill rod and parts with diffuse image. The BIPS-image quality is listed in Table 3-1.

Table 3-1. BIPS Image Quality.

From	To	% visible	Comment
59.4	64	40–50	Bad. 50–60% of image non-visible.
64	66.6	60–80	Acceptable. Both sides of image slightly diffuse. Part of image dark to black.
66.6	69.2	100	Good. Both sides of image slightly diffuse.
69.2	71.5	80–100	Acceptable. Part of image dark to black.
71.5	75.2	70–100	Good. image slightly diffuse.
75.2	87.8	40–60	Bad. Image diffuse.
87.8	116	50	Acceptable. Mud on lower side of borehole.
116	165.4	30–40	Bad. Mud on lower side of borehole.
165.4	166.34	10–30	Bad. Mud. Less than 30% of image visible.
166.34	498.5	80–100	Acceptable. Part of image dark to black. Partly slightly diffuse image.
498.5	925	50–80	Acceptable. Part of image dark to black. partly diffuse image.
925	927.87	0–50	Bad. Muddy.

4 Execution

4.1 General

Boremap mapping of the drill core KFM08D was performed and documented in accordance with the activity plan AP PF 400-06-116 (SKB, internal document) and the method description for Boremap mapping (SKB, MD 143.006, Version 2.0, Metodbeskrivning för Boremap-kartering, SKB, internal controlling document). The mapping was preceded by an overview documentation of the geology in the borehole by Kenneth Åkerström. All observations are made by ocular inspection, since no other data were available.

The mapping was performed in SKB's facilities in Forsmark between January 18th and March 28st in 2007 by Christin Döse, Gunnar Rauséus, Peter Dahlin, Emil Lundberg and Eva Samuelsson from Geosigma AB, Jan Ehrenborg, Mirab, Anders Wängnerud, Jesper Petersson and Ulf B Andersson from Vattenfall Power Consultant.

4.2 Preparations

The lengths registered during the BIPS-logging deviates from the true length, which usually increases with depth. Therefore length adjustments were made. The length of the BIPS-image was adjusted with reference to slots cut into the borehole wall approximately every 50th metre and with reference to the end of casing (see Table 4-1).

Geometrical data for the borehole is given in Table 4-2. Background data (Appendix 2) prior to the Boremap mapping included:

- Borehole diameter.
- Reference slots for length adjustments.
- Borehole deviation.

Table 4-1. Length adjustments.

Rec. length (m)	Adj. length (m)	Difference (m)
199.516	200	-0.484
249.327	250	-0.673
299.188	300	-0.812
349.073	350	-0.927
398.947	400	-1.053

898.557	900	-1.443

Table 4-2. Borehole data for KFM08D.

Mapping Nr	Mapping interval	Bearing (degrees)	Inclination (degrees)	Diameter (mm)	Borehole length (m)	BIPS-image interval (m)	End of casing
1	59.00–941.76	100.0	-55.0	77	942.3	59.0–927.87	

4.3 Execution of measurements

Concepts used during the core mapping, are defined in this chapter.

4.3.1 Fracture definitions

Definitions of different fracture types and apertures; crush zones and sealed fracture network are found in SKB MD 143.008 (Nomenklatur vid Boremapkartering, internal controlling document).

Two types of fractures are mapped in Boremap; broken and unbroken. Broken are fractures that split the core while unbroken fractures do not split the core. All fractures are described with their fracture minerals and other characteristics, e.g. width, aperture and roughness. Visible apertures are measured down to 1 mm in the BIPS-image. Smaller apertures, which are impossible to detect in the BIPS-image, are denoted a value of 0.5 mm. If the core pieces do not fit well, the aperture is considered “probable”. If the core pieces do fit well, but the fracture surfaces are dull or altered, the aperture is considered “possible”.

All fractures with apertures > 0 mm are treated as open fractures in the SICADA database. Only few broken fractures are given the aperture = 0 mm. Unbroken fractures usually have apertures = 0 mm. Unbroken fractures that have apertures > 0 mm are interpreted as partly open and are included in the open-category in SICADA. Open and sealed fractures are finally frequency calculated and shown in Appendix 1.

4.3.2 Fracture alteration and joint alteration number

Joint alteration number is principally related to the thickness of, and the clay content in a fracture /2/. Over 1 mm thick fractures rich in clay minerals are usually given joint alteration numbers between 2 and 4. The majority of the broken fractures are very thin to extremely thin and seldom contain clay minerals. These fractures receive joint alteration numbers between 1 and 2.

A subdivision of fractures with joint alteration numbers between 1 and 2 was introduced to facilitate both the evaluation process for fracture alterations and the possibility to compare the alterations between different fractures in the boreholes. The subdivision is in accordance with the subdivision introduced by Ehrenborg and Steiskal /3/.

4.3.3 Mapping of fractures not visible in the BIPS-image

Not all fractures are visible in the BIPS-image, and these fractures are oriented using the *guide-line method* /3/, with one modification. The orientation performed in this work is based on the following data:

- Amplitude (measured along the drill core) which is the interval between fracture extremes along the drill core.
- The relation between the rotation of the fracture trace and a well defined structure visible in both drill core and BIPS-image. This rotation is measured with measuring tape on the drill core.
- Absolute depth relative to a well defined structure visible in both drill core and BIPS-image.

The fractures mapped with the *guide-line method* are mapped as “non-visible in BIPS” and can therefore be separated from fractures visible in BIPS which probably have a more accurate orientation.

4.3.4 Definition of veins and dikes

A rock sequence that covers less than 1 m of the drill core is mapped as a “rock occurrence” in Boremap. Rock occurrences that cover more than 1 m of the drill core are mapped as a separate *rock type*.

Chiefly two different types of rock occurrences are mapped: veins and dikes. These two are separated by their respectively length in the drill core; veins are set to 0–20 cm and dikes are set to 20–100 cm if evidence for intrusion is visible in the drill core. If the rock occurrence cannot be classified as a vein or a dyke, the occurrence type is mapped as “unspecified”. In Forsmark there are boudinized veins, xenoliths, blobs etc and the occurrence type is usually difficult to determine from the drill core.

4.3.5 Mineral codes

In cases where properties or minerals are not represented in the mineral list, the following mineral codes have been used in the mapping of KFM08D:

- X1 = Bleached fracture walls.
- X2 = Interpreted grouting, which is only observed in the borehole wall and hence in the BIPS-image (not used in this borehole).
- X3 = The drill core is broken at a right angle and the broken surfaces have a polished appearance. This is caused by rotation of two core pieces along an intermediate fracture wearing away possible mineral filling. It is impossible to say whether this fracture was open or sealed in situ.
- X4 = Dull fracture surface, no visible fracture mineral.
- X5 = Fresh fracture surface, no detectable fracture mineral.
- X6 = Striated surfaces, probably slickensided.
- X7 = Saussurite.

4.4 Data handling

In order to obtain the best possible data security, the mapping was performed on the SKB network, with regular back-ups on the local drive in accordance with the consultants’ quality plan. Each day, a summary report was printed in order to find possible misprints. If misprints were observed, they were corrected before the mapping proceeded. A WellCad-diagram was also plotted before the drill cores were changed on the roller table. When the mapping was completed, data was checked once more for possible misprints. Before exporting data to SICADA, borehole lengths, mapping lengths, deviation data and length adjustments were checked again, and then the mapping was checked by a routine in Boremap which detects logical defects.

4.5 Nonconformities

4.5.1 Core loss

Core loss occurs in two sections: 340.08–340.10 m and 924.341–924.68 m.

4.5.2 Overrepresented fracture mineral

The occurrence of calcite in fractures is overrepresented relative to other minerals, since it is detected by reaction with diluted hydrochloric acid even though it is macroscopically invisible.

4.5.3 Fracture roughness and surface

The estimation of roughness of fractures in this work diverges rather much from the mappings by Vattenfall Power Consultant. For example: Geosigma considers more than half of fractures as undulating, while the remaining fractures are considered stepped, planar and irregular. The proportion of planar, undulating, stepped and irregular fractures in the mappings of Vattenfall Power Consultant is different. This is because the personal interpretation of the definitions of fractures /5/, since the definitions are made for another scale, i.e. for tunnels and excavations, and not for boreholes. Work has been started to synchronize the mapping teams.

4.5.4 Mapping without BIPS-image

The borehole section between 927.87–942.230 m was mapped without BIPS-image. All observations are mapped without orientation and located using the recorded length. This section is not included in the calculation of fracture frequencies and rock type proportions made in this report.

5 Results

The Boremap mapping of KFM08D is stored in SICADA and it is only these data that shall be used for further interpretation and modelling. The interpreter should be aware of the assumptions mentioned in Chapter 4.

Results from the Boremap mapping are briefly described in this chapter and the graphical presentation of the data is given in Appendix 1 (WellCad-diagram).

5.1 Rock type

The dominant rock type in KFM08D is a generally foliated metagranite-granodiorite (rock code 101057) followed fine- to medium-grained metagranitoid (rock code 101051) and pegmatitic granite (rock code 101061). Subordinate rock types are medium-grained metadiorit-gabbro (rock code 101033), amphibolite (rock code 102017), fine- to medium-grained granite (rock code 111058), felsic to intermediate metavolcanic rock (rock code 103076) and aplitic metagranite (rock code 101058). Rock type distribution listen in Table 5-1.

In areas with medium to strong albitization the rock type is difficult to determine. The determination has been done mainly with respect to grain-size and mica content. Rock type with aphanitic to fine grain-size and none to low mica content was mapped as aplitic metagranite (rock code 101058). Rock type with medium grain-size and spotted with mica was mapped as medium-grained metagranitoid (rock code 101057), and a medium to coarse grain-size was mapped as pegmatitic granite (rock code 101061).

5.2 Fractures and crushed sections

A total of 4,930 unbroken and 1,505 broken fractures were documented in KFM08D (59.44–927.87 m). Of the unbroken fractures, 31 show an aperture, while 219 of the broken fractures are considered artificial and have an aperture = 0. This results in the following interpreted fracture frequencies: 5.9 sealed fractures/m (sealed network excluded), 1.5 open fractures/m (crushed sections excluded) and 0.36 partly open fractures/m.

The open fractures, sealed fractures and sealed fracture networks are concentrated to the borehole intervals 184–210 m, 544–570 m, 582–609 m, 621–688 m, 737–570, 819–842 m and 900–942.3 m. The three borehole intervals 184–210 m, 582–609 m and 621–688 m also include fractures with apertures ranging up to 10 mm. The most frequent fracture minerals are chlorite, calcite, clay minerals and adularia.

A crushed core section occurs at 925.940–926.113 m borehole length. The fracture surfaces are highly altered with clay minerals.

Table 5-1. Rock type distribution (%) in KFM08D.

Borehole	101057	101051	101061	101033	102017	111058	103076	101058
KFM08D	78	9	5	3	3	2	< 1	< 1

5.3 Sealed brittle to ductile deformation

The rock types in borehole KFM08D show commonly weak to moderate foliation and lineation. The foliation is undulating in the borehole, but mostly striking S-SE (see Appendix 1). The intensity of the foliation in the borehole varies from weak to medium. In the parts of the borehole, lineation is dominating over foliation and shows a W-SW trend.

Narrow shear bands occur throughout the borehole, ranging from ductile to brittle in character. Deformation bands occur in the borehole interval 112–114 m (brittle to ductile), 202–210 m (brittle to ductile), 430–431 m (ductile), 455–456 m (ductile), 597–599 m (brittle to ductile) and 926–927 m (brittle to ductile).

5.4 Alteration

Three borehole intervals with generally medium to strong albitization occur at 395–580 m, 610–840 m and 926–942 m (this borehole interval is partly mapped without BIPS-image) /6/. These intervals also include sections with faint to medium oxidation.

Other alteration types are sporadic and usually very sparse. These are epidotization and chloritization. Chloritization occurs in three minor borehole sections 904–906 m (weak-strong), 910–912 m (weak) and 924–928 m (strong).

One minor section with quartz dissolution occurs at 932.62–932.68 m borehole length.

5.5 Core discing and inferred drilling induced features

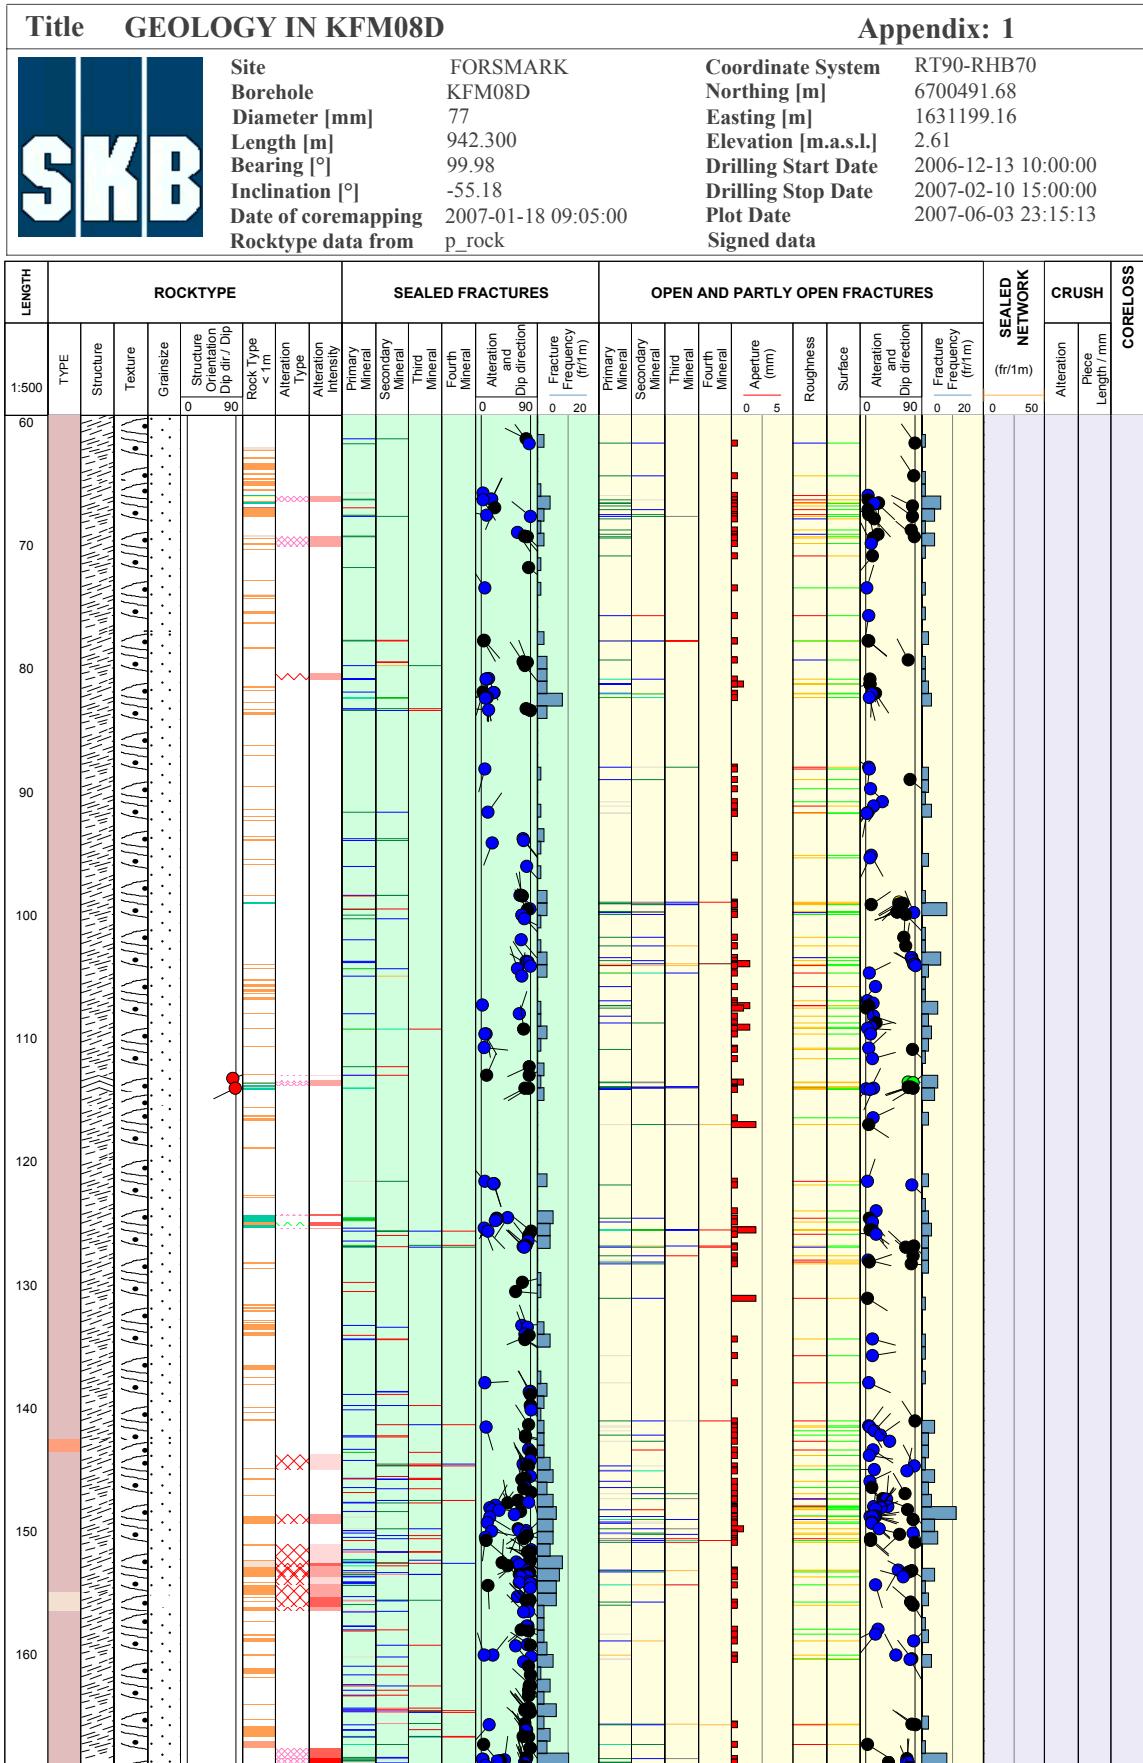

One minor section with core discing is observed at 328.27–328.59 m borehole length.

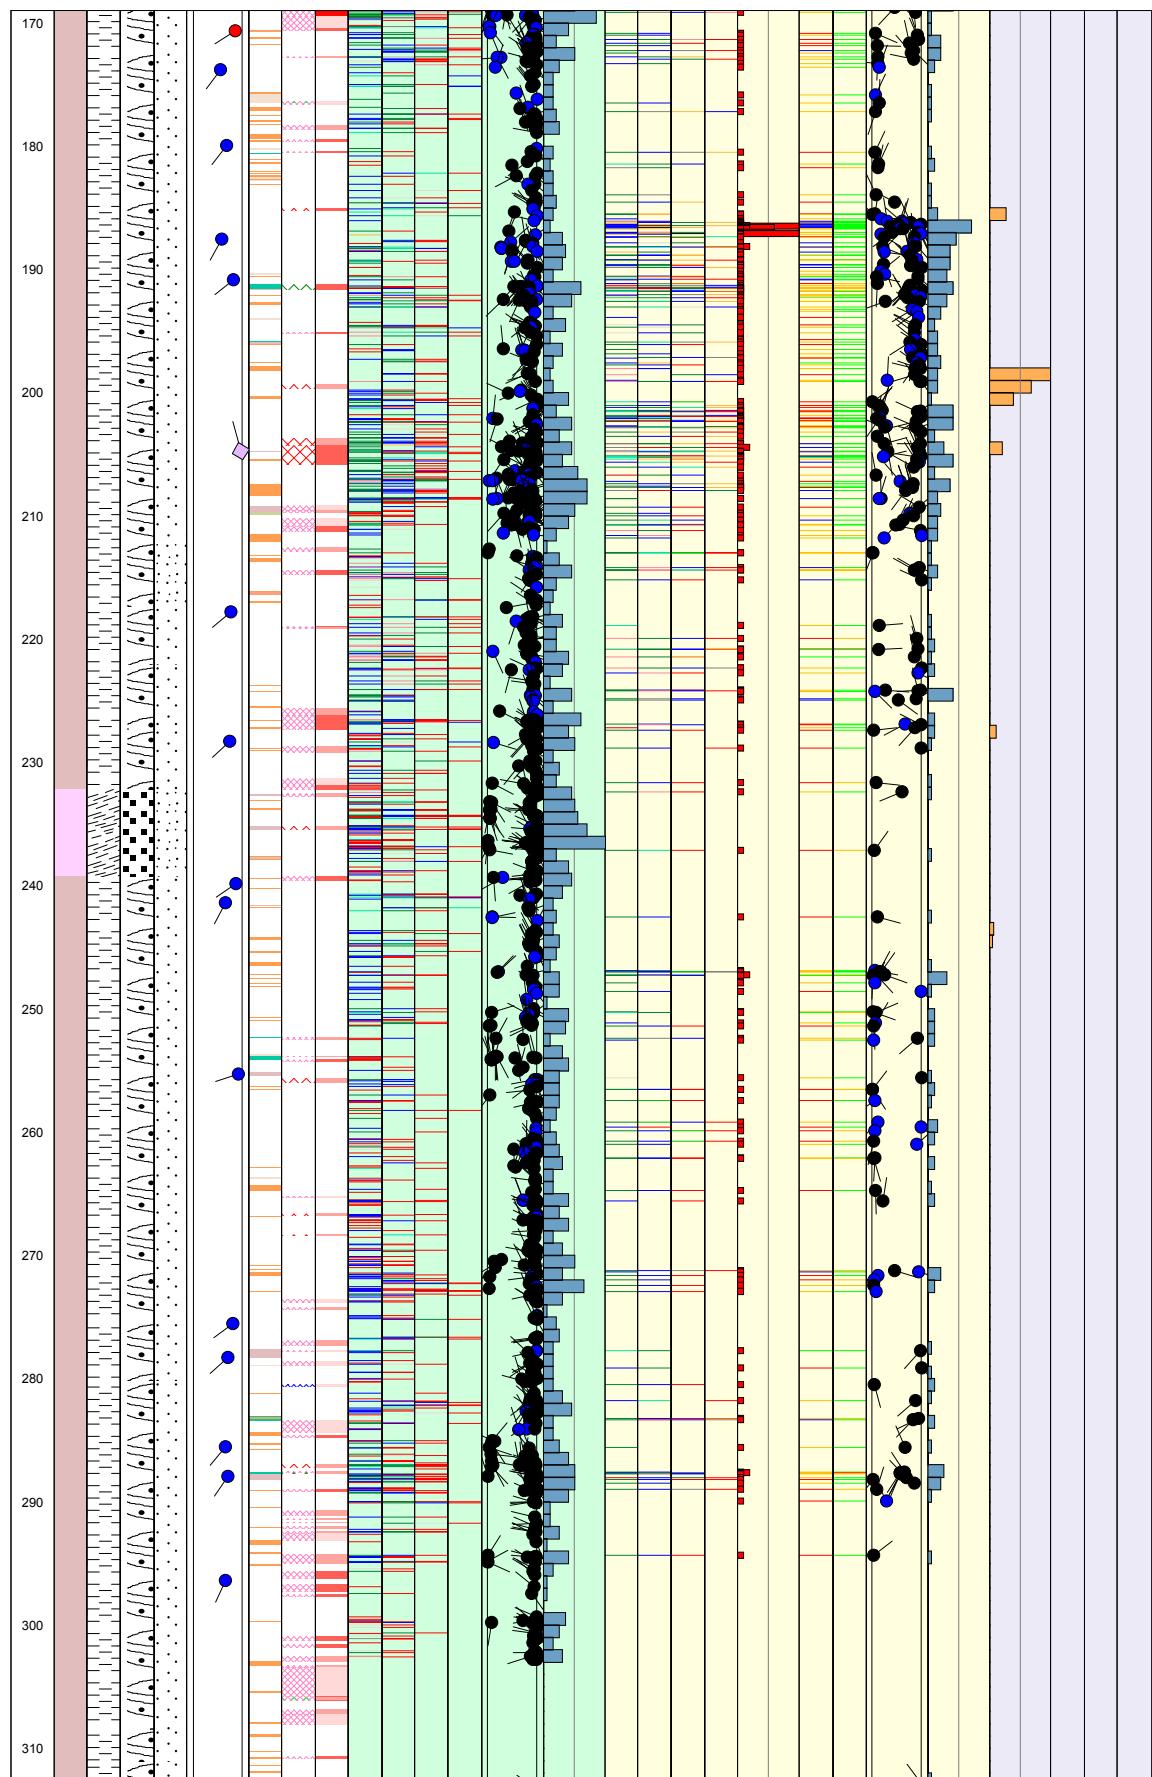

Drilling induced crush occurs at 417.13 m, 556.43 m, 556.47 m, 612.80 m, 905.45 m and 905.61 m borehole length.
