Keywords: Shallow ground water, Metals, Isotopes, Nutrients, Simpevarp, Sweden.

This report concerns a study which was conducted for SKB. The conclusions and viewpoints presented in the report are those of the author and do not necessarily coincide with those of the client.

Data in SKB's database can be changed for different reasons. Minor changes in SKB's database will not necessarily result in a revised report. Data revisions may also be presented as supplements, available at [www\(skb.se\)](http://www(skb.se)).

A pdf version of this document can be downloaded from [www\(skb.se\)](http://www(skb.se)).

Abstract

In 2006 sampling of shallow ground water in water wells in soil has been performed at 21 sites within the site investigation area at Oskarshamn. The purpose of the activity is to characterise the shallow ground water in the site investigation area.

Some physical and chemical parameters were measured directly in the field but most parameters were analysed at different laboratories. The ground water sampling activity consisted of one program, chemical programme class 5 (reduced).

The large number of sites and parameters analysed have generated a large amount of data, which will later be used for advanced analysis and modelling. In this report the evaluation aims to give a simple overview of the results and to describe the quality of the data sampled 2006.

Two nonconformities have occurred. Results from two samples were error coded in SICADA and omitted from this report. The reason stated was to high charge balance. The samples in question were the spring samples from the water wells SSM00041 and SSM00241. Further the evaluation of data for this report reviled one questionable result from the analysis of aluminum. The result 0.2 µg/l is about one thousand times lower than what can be expected from the site (SSM00034, sampled 2006-03-30).

The results showed a quite large variation between the different wells. The ion concentrations and conductivity ranged from what can be termed as low to high or very high values. Likewise the concentration of HCO₃ varied extensively throughout the investigation area with high concentrations in most wells. In two wells the concentration of HCO₃ was lower with an indication of a problem with acidification in the ground water.

As with the ions measurements on environmental metals and trace elements varied quite much between the wells. High concentration of lead in some of the wells indicated pollution but since the concentration of lead in the wells had a similar relation to aluminium as most other elements it was argued that the high concentration of lead probably can be explained by the natural composition of minerals within the site investigation area.

The average ratios of boron (¹⁰B/¹¹B) where similar in most wells and there seems to be low variation in the investigated area. With the exception of two sites the ratio of δ¹⁸O showed a good relationship with the conductivity (Figure 6-8). The two sites were SSM000241 and SSM000242 and these results might indicate occurrence of relict seawater at the two sites. The isotopes of δ³⁷Cl and δ³⁴S varied more between the different wells with the greatest variation in δ³⁴S.

The average hydrogen stable isotope ratios (δ²H) and tritium (³H) had similar values in most wells. However three wells differed with a markedly lower ratio for ³H. The δ²H ratio correlates well with the δ¹⁸O ratio. The linear relation differ markedly from the “Global Meteoric Line” (δ²H=8*δ¹⁸O+10) which is based on precipitation data.

The concentration of nitrate varied with considerable higher concentration in some of the wells. The concentration in these wells can be termed as moderately high according to Swedish environmental quality criteria. These results might indicate leakage from the surrounding farmland areas. The concentration of NH₄-N and PO₄-P varied with markedly higher values in the ground water wells situated close to the sea. The two sites SSM000241 and SSM000242 differed even more with extremely high values of NH₄-N and PO₄-P. The concentration of carbon (TOC and DOC) varied with results between 4 and 20 mg/l in most wells. The two wells SSM000241 and SSM000242 differed markedly with values between 70 and 75 mg/l.

Sammanfattning

Provtagning av ytligt grundvatten i jordrör har under 2006 skett vid 21 platser inom platsundersökningsområdet vid Oskarshamn. Målsättningen med aktiviteten är att karakterisera det ytliga grundvattnet i området.

Några fysiska och kemiska parametrar har mätts direkt i fält men merparten av de insamlade parametrarna är resultatet av laboratorieanalyser. Aktiviteten bestod av ett program, klass 5 (reducerat).

Det stora antalet platser och analyserade parametrar har genererat en stor mängd data som senare kommer att användas för avancerad analys och modellering. I denna rapport har utvärderingen syftat till att ge en enkel översikt över resultaten och att beskriva kvaliteten av de data som samlats in 2006.

Två avvikelse har identifierats. Resultaten från två prover har felmarkerats i SICADA och dessa resultat har uteslutits från denna rapport. Skälet var att jonbalansberäkningarna visat på ett allt för stort fel. De aktuella proverna var från vårprovtagningen i jordrör SSM00041 och SSM00241. Vidare visade utvärderingen av data till denna rapport ett tveksamt resultat för aluminium. Provet ifråga hade ett värde på 0,2 µg/l och kom från jordrör SSM00034 som provtogs 2006-03-30. Detta resultat är ungefärligen tusen gånger lägre än vad som kan förväntas i området.

Resultaten av undersökningarna visade på en ganska stor variation mellan de olika grundvattenrören i området. Koncentrationen av joner och konduktiviteten varierade mellan vad som kan betecknas som låga till väldigt höga värden. Likadant varierade koncentrationen av HCO_3^- mycket med höga koncentrationer vid de flesta provplatserna. I två av grundvattenrören var koncentrationen så låg att resultatet indikerade problem med försurning av grundvattnet.

Liksom för jonerna varierade värdena för miljömetaller och spårelement ganska mycket mellan de olika provplatserna. En hög koncentration av bly vid några av platserna indikerade någon sorts förorening. Men eftersom relationen mellan koncentrationen av bly och aluminium liknade den som flertalet andra metaller och spårelement hade med aluminium drogs slutsatsen att resultatet med höga blyhalter kan förklaras med mineralets naturliga sammansättning i området.

Isotopkvoterna av bor ($^{10}\text{B}/^{11}\text{B}$) var liknande vid de flesta provplatserna och det verkar vara en liten variation inom undersökningsområdet. Med undantag av två jordrör, SSM000241 och SSM000242, visade isotopen av $\delta^{18}\text{O}$ en god relation med konduktiviteten i vattnet. Dessa resultat kan indikera förekomst av relikt havsvatten vid de bågge platserna. Isotoperna av klor ($\delta^{37}\text{Cl}$) och svavel ($\delta^{34}\text{S}$) varierade mer med en något större variation för $\delta^{34}\text{S}$.

Medelvärdena av väteisotoperna deuterium ($\delta^2\text{H}$) och tritium (${}^3\text{H}$) var liknande i de flesta grundvattenrören. Resultatet från tre av rören skiljde sig dock med en märkbart lägre kvot för ${}^3\text{H}$. Kvoterna av $\delta^2\text{H}$ var väl korrelerade till kvoterna av $\delta^{18}\text{O}$ men den linjära relationen skiljde sig märkbart från "the Global Meteoric Line" vilken baseras på data från nederbörd.

Koncentrationen av nitrat varierade med betydligt högre värden i några av grundvattenrören. Dessa värden kan klassas som måttligt höga enligt Naturvårdsverkets kriterier. Koncentrationen av $\text{NH}_4\text{-N}$ och $\text{PO}_4\text{-P}$ varierade med märkbart högre halter i jordrören som ligger nära havet. Resultaten från de två jordrören SSM000241 och SSM000242 visade på vad som kan klassas som extremt höga halter av $\text{NH}_4\text{-N}$ och $\text{PO}_4\text{-P}$. Koncentrationen av kol (TOC and DOC) varierade med värden mellan 4 och 20 mg/l i de flesta jordrören. De två jordrören SSM000241 och SSM000242 hade ännu högre halter med värden mellan 70 och 75 mg/l.

1 Introduction

This document reports the data gained by sampling of shallow ground water 2006, which is one of the activities performed within the site investigation at Oskarshamn. The work was carried out in accordance with activity plans AP PS-400-04-024, AP PS-400-04-77 and AP PS-400-06-039. In Table 1-1 controlling documents for performing this activity are listed. The activity plan is an SKB's internal controlling document.

Within the site investigation area water has been sampled from shallow ground water wells in soil. During 2006 sampling was performed at 21 sites on up to four occasions (Figure 1-1). The water was analysed for a large number of parameters. All original results have been stored in the primary database SICADA. The results are traceable by the activity plan numbers. The data in the database will later be used for further interpretation (modelling).

Table 1-1. Controlling documents for the performance of the activity.

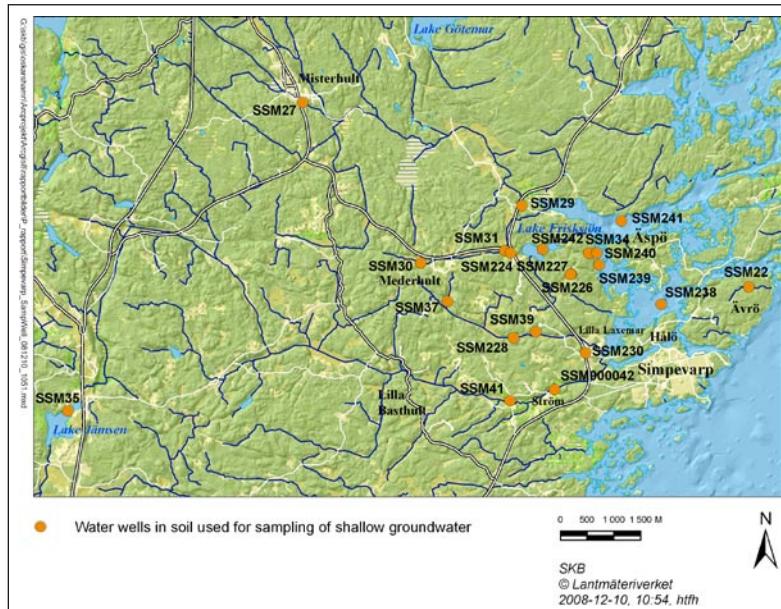

Figure 1-1. The site investigation area and the location of the water wells in soil used for sampling of shallow ground water in 2006.

2 Objective and scope

The purpose of the activity was to monitor and characterise the shallow ground water in the site investigation area. According to the activity plans sampling was planned to be performed at 21 different ground water wells, at one or more occasions during 2006. One of these water wells are situated in the Ävrö, Hälö and Simpevarp peninsula area, and 20 in the Laxemar area.

Some physical and chemical parameters were measured in the field. Water samples were then taken for analysis of further parameters. The samples were later sent to different laboratories for analysis.

In general the ground water sampling activity was done according to the programme chemical class 5 (reduced). Analysed parameters are presented in Table 2-1. If it was not possible to get a sufficient amount of water for analysis of all components a priority order was set up (Table 2-1). A time schedule for the sampling in 2006 in both areas is presented in Appendix 2.

The large number of sites and parameters analysed have generated a large amount of data, which will later be used for advanced analysis and modelling. In this report the evaluation aims to give a simple overview of the results and to describe the quality of the data sampled from January 2006 to December 2006.

Table 2-1. Analysed components and priority order when sampling ground water wells in the Simpevarp and Laxemar area 2006.

Chemical programme class 5 – reduced 2006			
Components	Priority	Optional components:	Priority
Alkalinity, pH, Conductivity	2	Deuterium, O-18	4
Anions (F ⁻ , Cl ⁻ , Br ⁻ , SO ₄ ²⁻)	3	Tritium	5

Archive	13	POP, PON and POC	10

3 Equipment

3.1 Equipment used in the field

Underwater pump (type 12 V Avimex) and 12 V vacuum pump. Used in the field for pumping up water from the ground water wells.

Volume graded five litre containers, used in field as collecting vessels. Acid rinsed vessels were used when sampling for analysis of Fe (II) + Fe (tot) and main components, trace elements, lantanoides and environmental metals.

Sounding apparatus, pH-meter and thermometer were used for field measurements.

Field notes.

3.2 Equipment used at the laboratory

Tube pump. Used in the laboratory to filter sampled water.

0.45 µm filter (PALL). Capsule filter used together with the tube pump.

0.45 µm membrane filter. Used together with the tube pump.

4 Execution

4.1 Sites and sampling frequency

The total number of sampled sites was 21 (Appendix 1). During 2006, sampling was performed at 20 sites situated in the Laxemar area and at one site (SSM000022) in the Ävrö, Hålö, and Simpevarp peninsula area (Appendix 2).

The ground water wells sampled in 2006 are presented in Appendix 3. During the year there was a change in sampling effort in the Laxemar area. It was decided that sampling should cease in many of the sampling wells after the May/June sampling period (AP-PS 400-06-039). Before the December sampling period it was also decided that sampling should commence in two ground water wells in the sea (SSM000240 and SSM000241).

4.2 Execution of sampling and treatment of samples

To avoid contamination all sampling was conducted with protective rubber gloves and great care was taken not to contaminate containers or equipment. The day before sampling, each ground water well was visited and water was pumped out, if possible, for at least 10 minutes. On the sampling day, the ground water level was sounded and noted. Field measurements of pH were then performed, before the collecting vessels were filled with water. The sample for analysis of DOC was filtered in field with a syringe and 0.45 µm filter.

After sampling in field the samples were taken to a preparation room where most of the samples were prepared before analysis (Table 4-1). The sample in the collecting bottles was divided into smaller bottles. Many of the samples were also prepared with different types of filtrations and/or different type of conservations. This was conducted with protective rubber gloves to minimise the risk of contamination.

Routines for storing and delivery of samples to the different analysing laboratories are presented in Table 4-2. Some of the samples were sent immediately at the end of each day and some were stored in a refrigerator or freezer till the end of the week, when they were sent to the laboratory.

During the year some changes of the methods used have occurred:

In March some new water wells were installed (SSM000238, SSM000239, SSM000240, SSM000241, SSM000242). In connection with the installation water samples were taken and analysed. These water wells were not to be sampled further.

In December a new decision was made and it was decided that the water wells SSM000240 and SSM000241 should be permanently added to the sampling program. It was also decided that the water for analysis of HS⁻ should not be filtered and that the reagents should be added to the Winkler bottles in the field.

4.3 Documentation

All activities were continuously documented. Notes were taken on field conditions, time of sampling, marking of samples and so forth. Any deviations from the normal routines were also noted and commented in a special report. Delivery notes with instructions on which components to analyse were always sent with the samples to the different laboratories.

After analysis data has continuously been reported from the laboratories. As a routine a first preliminary quality control of the data was performed before storing them in the database SICADA.

5 Nonconformities

Results from two samples were error coded in SICADA and omitted from this report. The reason stated was to high charge balance. The samples in question were the spring samples from the water wells SSM000041 and SS000241.

The evaluation of data for this report reviled one questionable result from the analysis of aluminum. The result 0.2 µg/l is about one thousand times lower than what can be expected from the site (SSM000034, sampled 2006-03-30).

6 Results

6.1 Primary results

All primary results from the laboratory analysis and from the field measurements are presented in Appendix 4 and 5.

6.2 Dissolved ions and conductivity

The concentrations of ions and the conductivity varied quite much between the sites (Table 6-1). Most of the sites with the highest concentrations of ions are situated close to the coast or under the seabed. The site SSM000042 which is situated quite far from the coast was an exception with comparably high concentrations of ions.

According to the Swedish Environmental Quality Criteria /Swedish Environmental Protection Agency 1999/ the chloride concentrations range from low to very high at different wells, with concentrations above 100 mg/l termed as high and above 300 mg/l termed as very high.

Table 6-1. Average concentration of major ions and conductivity in shallow ground water wells 2006. Figures in italic indicate that some or all individual values in the calculation were below the detection limit of the analysis.

Site number	Fe (II) (mg/l)	Fe (tot) (mg/l)	Na (mg/l)	K (mg/l)	Ca (mg/l)	Mg (mg/l)	Li (mg/l)

As a quality control the charge balance has been calculated for the samples. In some of the samples there was a positive deviation of more than 10 percent (Table 6-2). This could indicate analytical problems or significant concentrations of negative ions which were not included in the calculation of the charge balance. Samples with high positive deviation in charge balance had all comparatively low conductivity though (Figure 6-1). This might be an indication of an occurrence of ions not included in the calculation of charge balance instead of analytical errors. One possible example is organic anions which has not been included in the calculations. In one case (Table 6-2) there was a negative deviation of more than ten percent. Likewise this could indicate an analytical problem or a significant concentration of a positive ion not included in the calculation.

Table 6-2. Samples with a charge balance which deviates more than 10 percent. Sampling in shallow ground water wells 2006.

Site number	Sampling date	Sample number	Charge balance (%)
SSM000027	2006-05-23	11074	20.61
SSM000035	2006-05-23	11075	10.97

SSM000228	2006-03-23	10931	11.18
SSM000241	2006-12-13	11588	-15.96

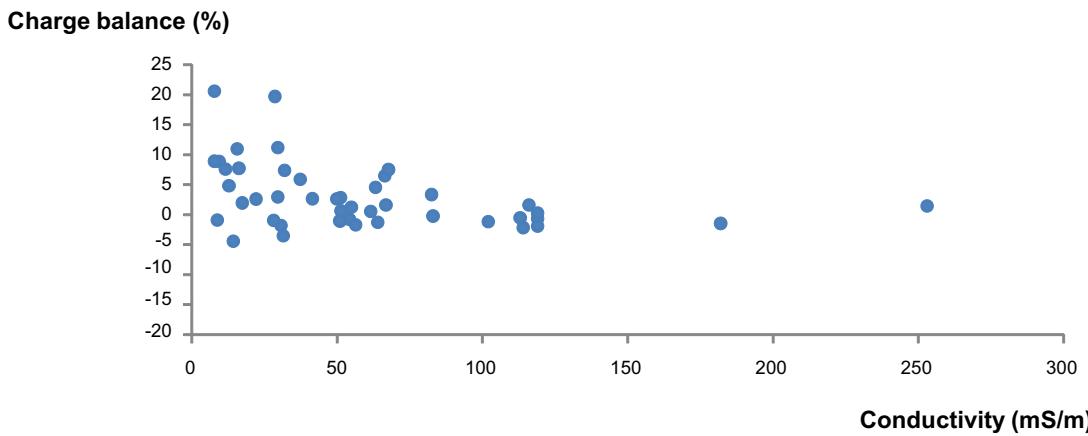

Figure 6-1. Relation of charge balance and conductivity in samples from all ground water wells 2006.

6.3 Acidification

As with other ions the concentration of HCO_3 varied extensively throughout the investigation areas (Table 6-3). In most wells the average concentration of HCO_3 was higher than 60 mg/l which is termed as a high or very high concentration according to the Swedish Environmental Quality Criteria /Swedish Environmental Protection Agency 1999/. In two wells (SSM000027 and SSM000227) the concentration of HCO_3 was lower than 10 mg/l which is termed as very low concentrations according to the Swedish EQC. In the latter cases the result is an indication of a problem with acidification in the ground water.

The field measurements of pH were in most cases considerably higher than the laboratory measurements (Table 6-3 and Figure 6-2). In most ground waters the opposite is normal due to a shift in the carbonate system when the gas pressure in the water is equalised prior to the analysis in the laboratory. An explanation to the observed results might be high contents of inorganic manganese and iron which is oxidised when the water is aerated prior to the analysis. Since there is both a very poor relation between the field and the laboratory measurements of pH and a very poor relation between the field measurements of pH and the concentration of HCO_3 (Figure 6-3) the best explanation is probably analysis errors. If this is true it is most likely the field measurements of pH that are faulty.

6.4 Environmental metals and trace elements

The results of measurements on environmental metals and trace elements are presented as average concentrations in Tables 6-4 and 6-5. The results varied quite much between the wells but most elements had a strong relation with aluminium, examples are shown in Figure 6-4. This indicates a good quality of the analysis performed. However, in some cases apparent outliers exists indicating pollution, contamination or analytical errors. Two examples are Zn and Cu in well SSM000230 (sample number 10897 and 11069) (Figure 6-5).

Some of the environmental metals can be classified according to the Swedish Environmental Quality Criteria's /Swedish Environmental Protection Agency 1999/. According to these criteria's the concentration of Cd and Zn was low to moderately high in the different wells. These results are what to be expected in an unpolluted area. However, the concentration of Pb were high ($> 3 \mu\text{g/l}$) in some of the wells (Table 6-4b and Figure 6-6). This could be an indication of some kind of pollution However the relation to aluminium is similar to most other elements and therefore the high concentration of Pb in these wells can probably be explained as a natural composition of the mineral in the site investigation area.

Table 6-3. Average concentration of HCO_3 , calculated alkalinity (HCO_3) and pH in shallow ground water wells 2006.

Site number	HCO_3 (mg/l)	Alkalinity (meq/l)	pH-lab	pH-field

6.5 Isotopes

The results of the measurements of isotopes are presented in Table 6-6. The average ratios of boron ($^{10}\text{B}/^{11}\text{B}$) where similar in most wells and there seems to be low variation in the investigated area. With the exception of two sites the ratio of $\delta^{18}\text{O}$ showed a good relationship with the conductivity (Figure 6-7). The two sites were SSM000241 and SSM000242 and these results might indicate occurrence of relict seawater at the two sites. The isotopes of $\delta^{37}\text{Cl}$ and $\delta^{34}\text{S}$ varied more between the different wells with the greatest variation in $\delta^{34}\text{S}$.

The average hydrogen isotope ratios of $\delta^2\text{H}$ and $\delta^3\text{H}$ had similar values in most wells. However the wells SSM000022, SSM000241 and SSM000242 differed with a markedly lower ratio for $\delta^3\text{H}$. The $\delta^2\text{H}$ ratio correlates well with the $\delta^{18}\text{O}$ ratio (Figure 6-8). The linear relation differ markedly from the “Global Meteoric Line” ($\delta^2\text{H}=8\times\delta^{18}\text{O}+10$) which is based on precipitation data.

6.6 Nutrients and carbon

The concentration of nitrate varied with considerable higher concentration in some of the wells (Table 6-7). According to the Swedish Environmental Quality Criteria /Swedish Environmental Protection Agency 1999/ the concentration of nitrate was moderately high (1–5 µg/l) in these wells. These results might indicate leakage from the surrounding farmland areas. The concentration of $\text{NH}_4\text{-N}$ and $\text{PO}_4\text{-P}$ varied with markedly higher values in the ground water wells situated close to the sea. The two sites SSM000241 and SSM000242 differed even more with extremely high values of $\text{NH}_4\text{-N}$ and $\text{PO}_4\text{-P}$. The concentration of carbon (TOC and DOC) varied with results between 4 and 20 mg/l in most wells (Table 6-7). Again the two wells SSM000241 and SSM000242 differed markedly with values between 70 and 75 mg/l.

Table 6-6. Average ratio of isotopes in shallow ground water wells 2006. Measurements not performed is marked with.
