# 1 Introduction

Since 2002, SKB investigates two potential sites for a deep repository in the Swedish Precambrian basement. In order to characterise the rock mass down to a depth of about 1 km at one of these sites, the Forsmark test site area, SKB has initiated a drilling program with three deep telescopic boreholes (Figure 2-1). Each borehole starts with 100 m of percussion drilling, and is followed by core drilling down to about 1000 m depth.

A detailed mapping of the material obtained through the drilling program is essential for a more specific sampling and for three-dimensional modelling of the site geology. For the purpose, the so-called Boremap system has been developed. The system integrates information from drill core mapping, alternatively, drill cuttings when a core is not available, with results from BIPS-logging (Borehole Image Processing System) and calculates the absolute position and orientation of fractures and lithological markers.

This report presents the results from the Boremap-mapping of telescopic borehole KFM01A, the first deep borehole drilled in the Forsmark candidate area (for location see Figure 2-1). In addition, it draws the attention to some of the limitations of the Boremap system.

## 2 Objective and scope

The aim of this activity is to obtain a detailed documentation of *all* structures and lithologies intersected by telescopic borehole KFM01A. This in turn will serve as a platform for forthcoming investigations (i.e. laboratory tests) of the drill core, as well as site descriptive modellings.

**Figure 2-1.** Location of telescopic drilled borehole KFM01A in the Forsmark test site area.

## **3 Equipment**

### **3.1 Description of equipment**

All BIPS-based mapping was performed in Boremap v. 3.0 and revised in v. 3.2. This software was loaded with the bedrock and mineral standard used by the Geological Survey of Sweden for surface mapping at the Forsmark investigation site to enable correlation with the surface geology. Additional software used during the course of the mapping was BIPS Viewer v. 1.10 and Microsoft Access. The final data presentation was made using Stereonet and WellCad v. 3.2.

The following equipment was used to facilitate the core mapping: folding rule, hydrochloric acid, knife, water-filled atomizer, hand lens and sandpaper.

## **4 Execution**

Telescopic borehole KFM01A starts with 100 m of percussion drilling, followed by core drilling down to about 1001.5 m depth. The soil cover is about 12 m. The bedrock data available from the upper, percussion drilled part of KFM01A are limited to about 20 m of BIPS-imaging (29.45–51.15 m) and drill cuttings collected at 3 m intervals between 12 and 100 m depth. These samples were mapped by Johan Kjellman (Department of Earth Sciences, Uppsala University) prior to the start of Boremap-mapping, and the data are stored in SKB's database SICADA (field note Forsmark 26; Appendix 6). Some of the drill cutting samples were, however, re-examined during the Boremap-mapping to back up the BIPS-mapping.

During the mapping, the 900 m drill core obtained from the interval 100.0–1001.5 m was available in its entirety on roller tables in the core-mapping accommodation at Forsmark (the Lentab hall, near the SKB/SFR-office at Forsmark). The BIPS-based mapping was preceded by an initial separation of induced and natural fractures made by Allan Stråhle (Geosigma). In addition, Eva-Lena Tullborg (TerraLogica) provided XRD analysis of the core fracture filling mineralogy, whereas SGU provided modal analyses of the principal core lithologies as well as reference samples from the surface mapping.

The mapping of KFM01A was done in Boremap v. 3.0 according to the SKB method description for Boremap-mapping, SKB MD 143.006 (v. 1.0; SKB internal controlling document), with the exception that no geophysical logs were available.

### **4.1 Preparations**

The borehole length registered in the BIPS-image deviates from the true borehole length with increasing depth, and the difference at the bottom of the borehole is about 5 m. It was, therefore, necessary to adjust the length with reference to groove millings cut into the borehole wall every 50th meter. The exact level of each reference mark can be found in SKB's database SICADA (Appendix 5). Unfortunately, reference marks are not visible in the BIPS-image at 450, 850 and 950 m depth, and the correction had to rely on values obtained through linear extrapolation. This may contribute to the fact that the adjusted length still is not completely identical with the one given at the drill core. In some intervals the difference may amount to some decimetres. After adjustment, the BIPS-image from the cored interval covers the depth between 102.03 and 1001.16 m.

The BIPS-image from the upper, percussion drilled 100 m, covers only about 20 m, from 29.45 to 51.15 m depth, due to an obstacle at 51.15 m which prevented further BIPS-logging. No length adjustment was done for this image, as the deviation from the true length is considered to be negligible at such shallow depths.

Data necessary for the calculations of absolute orientation for structures in the borehole includes borehole diameter, azimuth and inclination, and this data was collected from SKB's database SICADA (Appendices 3 and 4). Corrections for the deviation were done every twelfth meter.

## **4.2 Data handling**

To obtain the best possible data security, the mapping was performed on the SKB intranet, with regular back ups on the local drive.

The mapping was quality checked by a routine in the Boremap software before it was archived. The data was subsequently exported to the SKB database SICADA and stored under field note Forsmark 104 (Boremap-mapping) and field note Forsmark 26 (mapping of drill cuttings).

## **4.3 Analysis and interpretation**

The Boremap system has obviously some limitations, since all geological features must be represented by intersecting planes. Non-planar structures, such as small scale folding, linear objects (mineral lineations) and curved fractures can, therefore, not be correctly documented. The major problem is curved structures (e.g. fractures) which run almost parallel with the borehole axis. During the mapping of KFM01A, such features were approximated by fitting the plane after one of their ends, usually the upper, in the borehole. The fact that the structure did not actually intersect the borehole is only noted in the attached comment.

Another problem is geological features (mainly fractures) observed only in the drill core. This problem usually arises from a poor resolution in the BIPS-image, which in the present case was caused by the presence of brownish black coatings on the borehole walls. Moreover, the BIPS-camera seems to have closed down in the interval 670.78–674.65 m. However, even in the most perfect BIPS-image, it is sometimes difficult to distinguish a thin fracture sealed by a low contrast mineral. All fractures and lithological contacts observed in the drill core, but not in the BIPS-image, have been registered as perpendicular to the borehole axis regardless of their actual orientation. The consequence is an overrepresentation of the subhorizontal fracture set.

A large amount of the steeply dipping fractures intersected by KFM01A are sealed by laumontite (a calcium zeolite). This sealing tends to expand, and eventually crackle in the drill core. As a consequence, some fractures mapped as natural (i.e. a fracture which is unsealed in the drill core) may in fact represent originally sealed fractures. All laumontite filled fractures suspected to have been sealed prior to drilling are mapped as sealed.

Even if reliable measurements of fracture widths/apertures less than 1 mm would be possible in the drill core, it is well beyond the BIPS-image resolution. For that reason, the minimum width/aperture given is 1 mm.

Joint alteration ( $J_a$ ) values used for natural fractures in KFM01A range between 1 and 4. However, later experience has shown that values for individual fractures generally are somewhat low: fractures with very thin chlorite or clay mineral coatings were given  $J_a$  values of 1, when values of 2 or 3 probably would have been more suitable.

In some intervals, the mapping was somewhat hampered by the occurrence of brownish black coatings on the borehole walls (mentioned above). The coating occurs sporadically throughout the core drilled part of the borehole, and typically forms a spiral pattern along the borehole axis with a pitch ratio of about 12–13 cm (Appendix 2). This

phenomenon is obviously drill induced, although the mechanism behind it is not fully understood. One plausible explanation is that the coatings originate from metal fragments abraded from the drill pipes, and that the spiral pattern is a consequence of wobbling of the pipe string in the borehole.

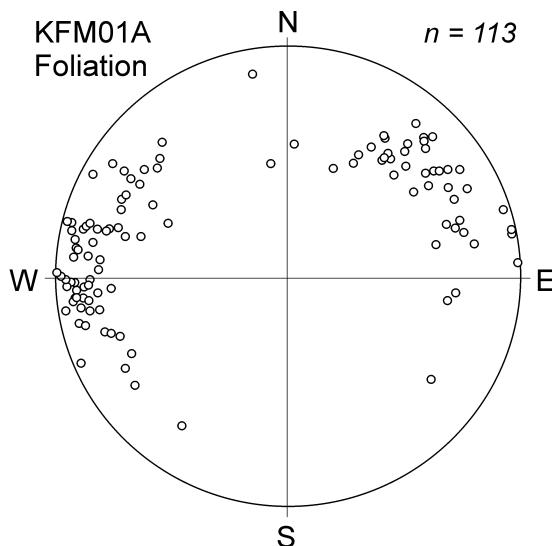

## 5 Results

### 5.1 Core lithology

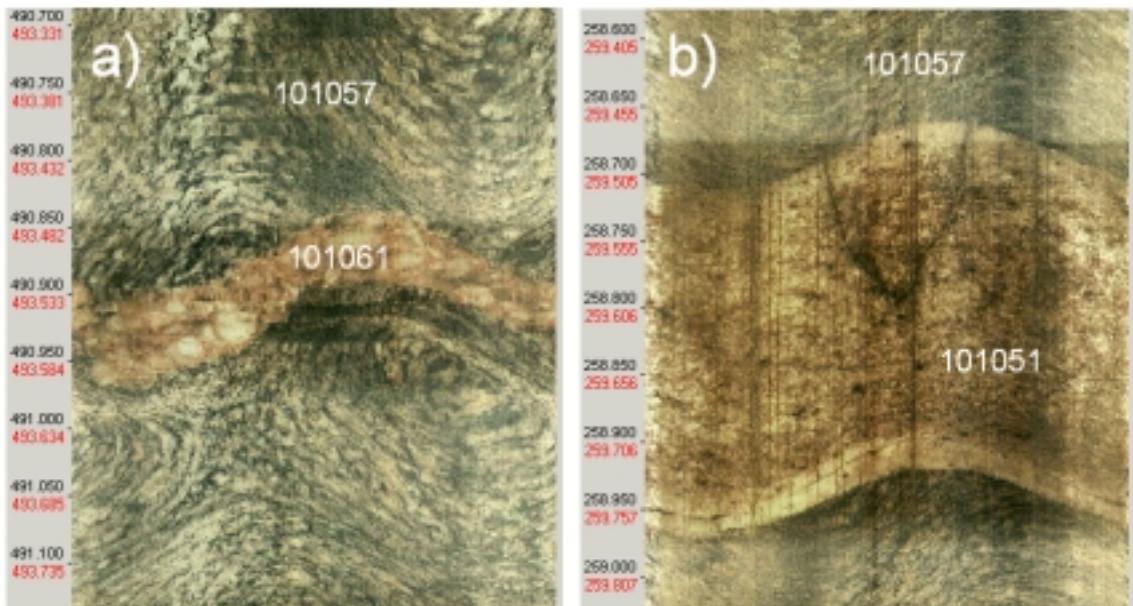

The far most abundant rock in borehole KFM01A is a medium-grained, reddish-grey to grey metagranodiorite-granite (rock code 101057). Other rock units, including finer grained metagranitoids, pegmatitic granites, amphibolites and minor bands, dykes or veins of leucogranitic material, are ubiquitous though volumetrically subordinate. With a few exceptions, all these rocks exhibit a moderate to steep ductile foliation, striking roughly between NW and NNE (Figure 5-1). However, a more random orientation due to small scale folding may occur adjacent to lithological discontinuities such as veins or minor dykes (Figure 5-2a).

The medium-grained metagranodiorite-granite is equigranular, foliated and locally shows a distinct, gently dipping mineral lineation. Typically it is light grey in colour, although more reddish varieties do occur, especially in the upper few hundred metres of the borehole. Minor sections speckled by fine grains of whitish plagioclase occur sporadically.

Fine-grained, equigranular metagranitoids (rock code 101051) occupy less than 4 % of the cored interval. They are grey, or more rarely light greyish-red, in colour and occur in intervals with a typical length of a few metres, surrounded by the coarser metagranodiorite-granite. Most of them show a weaker mineral foliation than the surrounding metagranodiorite-granite. Their external contacts are largely parallel with the tectonic foliation, except at two locations, at 898.51 and 937.34 m, suggesting that at least some of the finer grained metagranitoids are younger than the main phase of the ductile deformation (Figure 5-2b).

**Figure 5-1.** Lower hemisphere equal-area stereographic projections showing poles to ductile foliation planes intersected by borehole KFM01A.

**Figure 5-2.** BIPS-images from borehole KFM01A. a) Small scale, non-cylindrical folding of the metagranodiorite-granite, adjacent to a vein or thin dyke of pegmatitic granite (493.32–493.76 m depth). b) Dyke of equigranular, fine-grained granitoid cross-cutting the foliation of the surrounding metagranodiorite-granite (259.38–259.83 m depth).

Minor dykes, veins and patches of pegmatite, pegmatitic granite and leucogranitic material are frequent throughout the borehole, especially in lithological contacts. Except for one major occurrence at 525.2–534.5 m depth with pegmatitic granite, they are all less than 1 m in width, and most of them are thinner than about 1 dm. Typically they are texturally heterogeneous, with highly variable grain size, and some have quartz dominated cores. Their orientation varies widely, although a slight majority strike parallel or sub-parallel to the tectonic foliation. Also the intensity of the foliation varies, but it is generally weaker than in the wall rock, and in a few minor pegmatites not even distinguishable. Despite the obvious temporal span within this group, including at least three different pegmatite/aplite generations, these rocks were grouped as “pegmatite, pegmatitic granite” (101061) or “fine- to medium-grained granite” (111058).

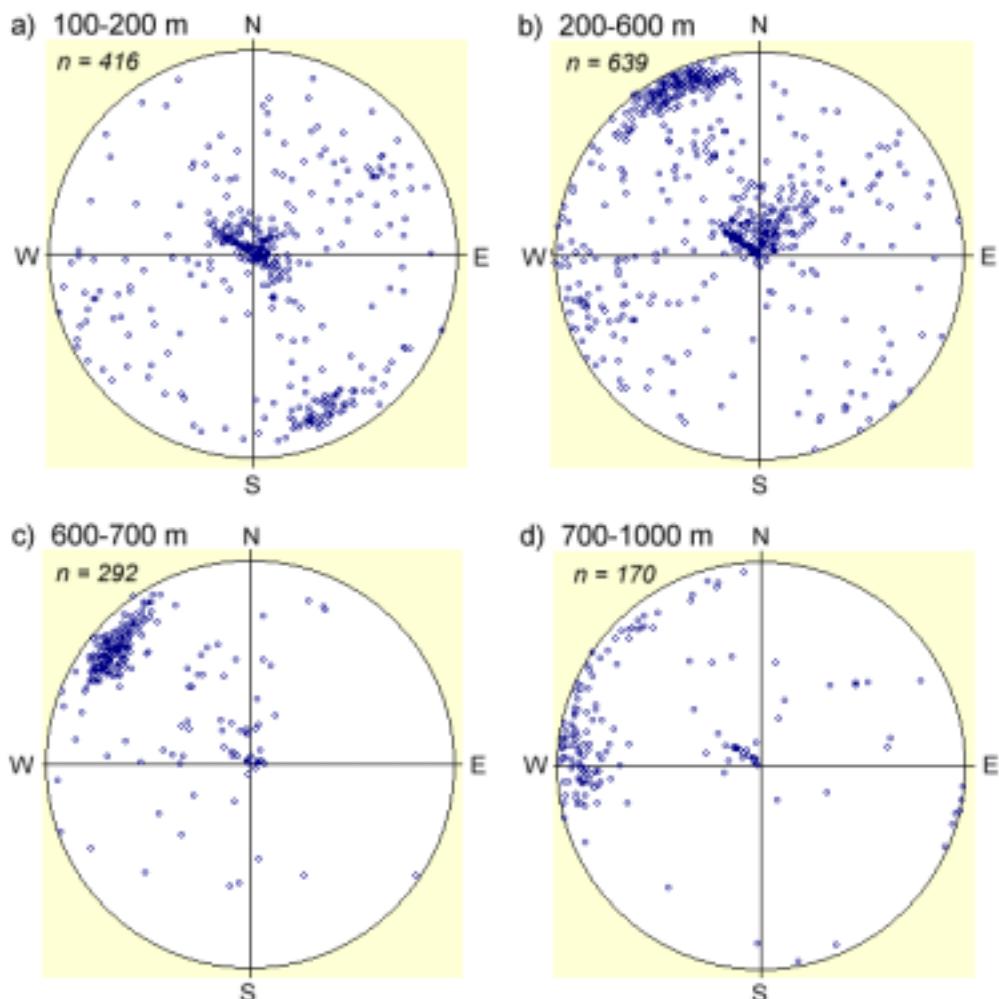

Amphibolites (rock code 102017) are estimated to occupy about 3 % of the cored interval. Their extension and contacts are more or less always parallel with the tectonic foliation. The majority is fine-grained, equigranular, and with a large proportion of biotite. Two anomalous, around 5 cm wide, ultramafic and more medium grained occurrences (coded 101004) were found in the depth interval 536.45–536.75 m.

Calc-silicate or skarn-like material (rock code 108019), often intimately associated with minor amounts of leucogranitic material, occurs at four intervals in the cored section: 611.6–613.1 m, 707.9–709.4 m, 863.2–863.9 m and 987.6–989.6 m.

## 5.2 Fractures

With the exception for a highly fractured zone in the depth interval 656–674 m, there is a conspicuous concentration of fractures in the upper 300 m of KFM01A. The orientation of these shallow fractures varies considerably, though the majority belong to a horizontal to sub-horizontal set, as can be seen in Figure 5-3a and b. Some fractures in this sub-horizontal set appear to be hydraulically open in the BIPS-image, though the aperture is normally less than a few millimetres. The infilling minerals are typically calcite and/or chlorite which form thin coatings on the fracture walls.

It should be noted that fractures mapped in the core that could not be found in the BIPS-image are all classified to fall into this sub-horizontal group of fractures. Due to the slight curvature of the borehole axis, the poles to these fracture planes form a short, but distinct array in the NW quadrant of the stereographic projections (Figure 5-3).

**Figure 5-3.** Lower hemisphere equal-area stereographic projections showing the poles to sealed and natural fracture planes within borehole KFM01A: a) 100–200 m depth, b) 200–600 m depth, c) 600–700 m depth, and d) 700–1000 m depth.

A second, well defined fracture set is recognized as generally sub-vertical fractures sealed by laumontite and chlorite. The average width of these fractures is 1–2 mm, with individual fractures ranging up to 5 mm. The occurrence of oxidized walls is more or less limited to this set. Down to about 200 m depth this set strikes ENE and dips steeply towards the north (Figure 5-3a). Below 200 m depth, the dip overturns towards south (Figure 5-3b) and with increasing depth the strike gradually becomes more northerly (Figure 5-3c and d). This set of fractures predominates below 600 m depth. The highly fractured zone intersected at 656–674 m depth, with fracture orientations around N30–65°W/70–85°SE, belongs to this set.

In addition to the well-defined sub-vertical and near horizontal sets of fractures described above, there is a third group of NW striking fractures with variable, but mostly moderate dips (40–70°). These NW striking fractures are mainly confined to the upper 600 m of the borehole.

It is, moreover, noteworthy that very few fractures in KFM01A have a measurable displacement that could indicate that they have been active as shear planes.

The only two, hydraulically open crush zones found during the mapping occur in the percussion drilled part of KFM01A.

Lithological contacts provide mechanical discontinuities in the drill core. It is hence reasonable to expect that high contrast in competence, such as between granitic material and amphibolite, may focus fracture formation. However, only about 10 % of the contacts between the amphibolites and the surrounding metagranodiorite-granite are fractured. Almost all of these fractures are natural and there is nothing to suggest that their occurrence is depth dependent.

### 5.3 Discussion

Direct correlation between the top surface geology and the lithology in KFM01A is somewhat hampered by the poor bedrock exposure in the area immediately surrounding the drill site. A thick Quarternary cover and irregular bedrock topography did not allow stripping. However, the general picture is that the core lithology corresponds well with what is to be expected from the regional surface mapping made by the SGU during 2002, though the rock proportions differ slightly /1/. Also the ductile features, including the near-horizontal lineation and steep, NW–NNE striking foliation, are in close agreement with the structural pattern which emerged from SGU's surface mapping in the area /1/. The core fracture pattern, on the other hand, gives a somewhat more ambiguous picture, as some of the more distinct, steep fracture sets (e.g. the NW-set) known in the region /2/ are highly underrepresented in the borehole. The most plausible explanation to this is the orientation of the borehole, plunging steeply towards NW. Another noteworthy feature, considering that epidote and quartz dominate the fracture filling assemblage at surface /1/, is the deficiency of epidote sealing in the borehole. This might probably be due to that epidote, and to some extent quartz, only occurs in steep fractures, which not have been intersected by the borehole.

**Title** LEGEND FOR FORSMARK KFM01A

<b>Site</b>	FORSMARK
<b>Borehole</b>	KFM01A
<b>Plot Date</b>	2003-04-07 18:21:01

**ROCKTYPE FORSMARK**

- Granite, fine- to medium-grained
- Pegmatitic, pegmatic granite
- Granitoid, metamorphic
- Granite, granodiorite and tonalite, metamorphic, fine- to medium-grained
- Granite, metamorphic, aplitic
- Granite to granodiorite, metamorphic, medium-grained
- Granodiorite, metamorphic
- Tonalite to granodiorite, metamorphic
- Diorite, quartz diorite and gabbro, metamorphic
- Ultramafic rock, metamorphic
- Amphibolite
- Calc-silicate rock (skarn)
- Magnetite mineralization associated with calc-silicate rock (skarn)
- Sulphide mineralization
- Felsic to intermediate volcanic rock, metamorphic
- Mafic volcanic rock, metamorphic
- Sedimentary rock, metamorphic

**STRUCTURE**

- Schistose
- Gneissic
- Mylonitic
- Ductile Shear Zone
- Brittle-Ductile Zone
- Veined
- Banded
- Massive
- Foliated
- Brecciated

**TEXTURE**

- Hornfelsed
- Porphyritic
- Ophitic
- Equigranular
- Augen-Bearing
- Non\_equigranular

**GRAINSIZE**

- Aphanitic
- Fine grained
- Fine to Medium Grained
- Medium coarse
- Coarse grained
- Medium grained

**STRUCTURE ORIENTATION**

- Massive
- Bedded
- Gneissic
- Schistose
- Brittle-Ductile Shear Zone
- Ductile Shear Zone
- Lineated
- Banded
- Viened
- Brecciated
- Foliated
- Mylonitic

**ROCK ALTERATION**

- Oxidized
- Cloritized
- Epidotized
- Weathered
- Tectonized
- Sericitized
- Miarolitic
- Silicification
- Argillization
- Albitization
- Carbonatization
- Saussuritization
- Steatitization
- Uralitization

**MINERAL**

- Hematite
- Calcite
- Chlorite
- Quartz
- Pyrrhotite
- Malachite
- Unknown
- Pyrite
- Clay Minerals
- Laumontite
- Prehnite
- Oxidized Walls

**INTENSITY**

- No intensity
- Faint
- Weak
- Medium
- Strong

**FRACTURE ALTERATION**

- Slightly Altered
- Moderately Altered
- Highly Altered
- Completely Altered
- Gouge
- Fresh

**ROUGHNESS**

- Planar
- Undulating
- Stepped
- Irregular

**SURFACE**

- Rough
- Smooth
- Slickensided

**CRUSH ALTERATION**

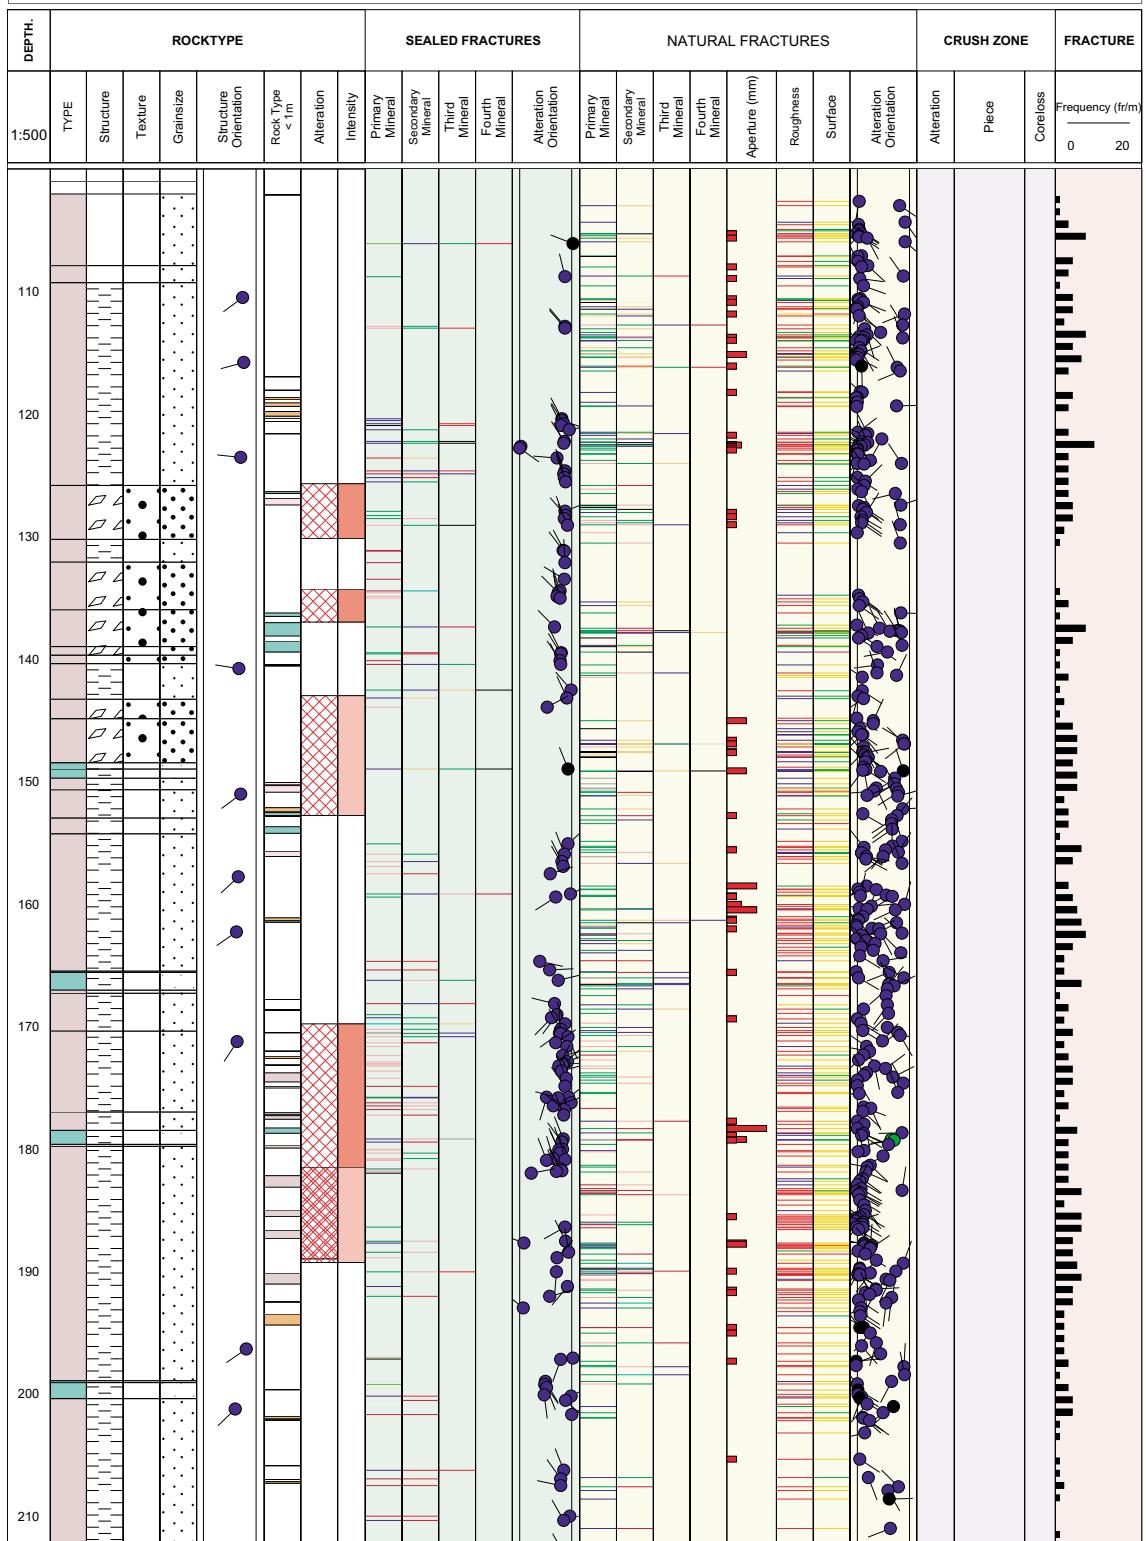

- Slightly Altered
- Moderately Altered
- Highly Altered
- Completeley Altered
- Gouge
- Fresh

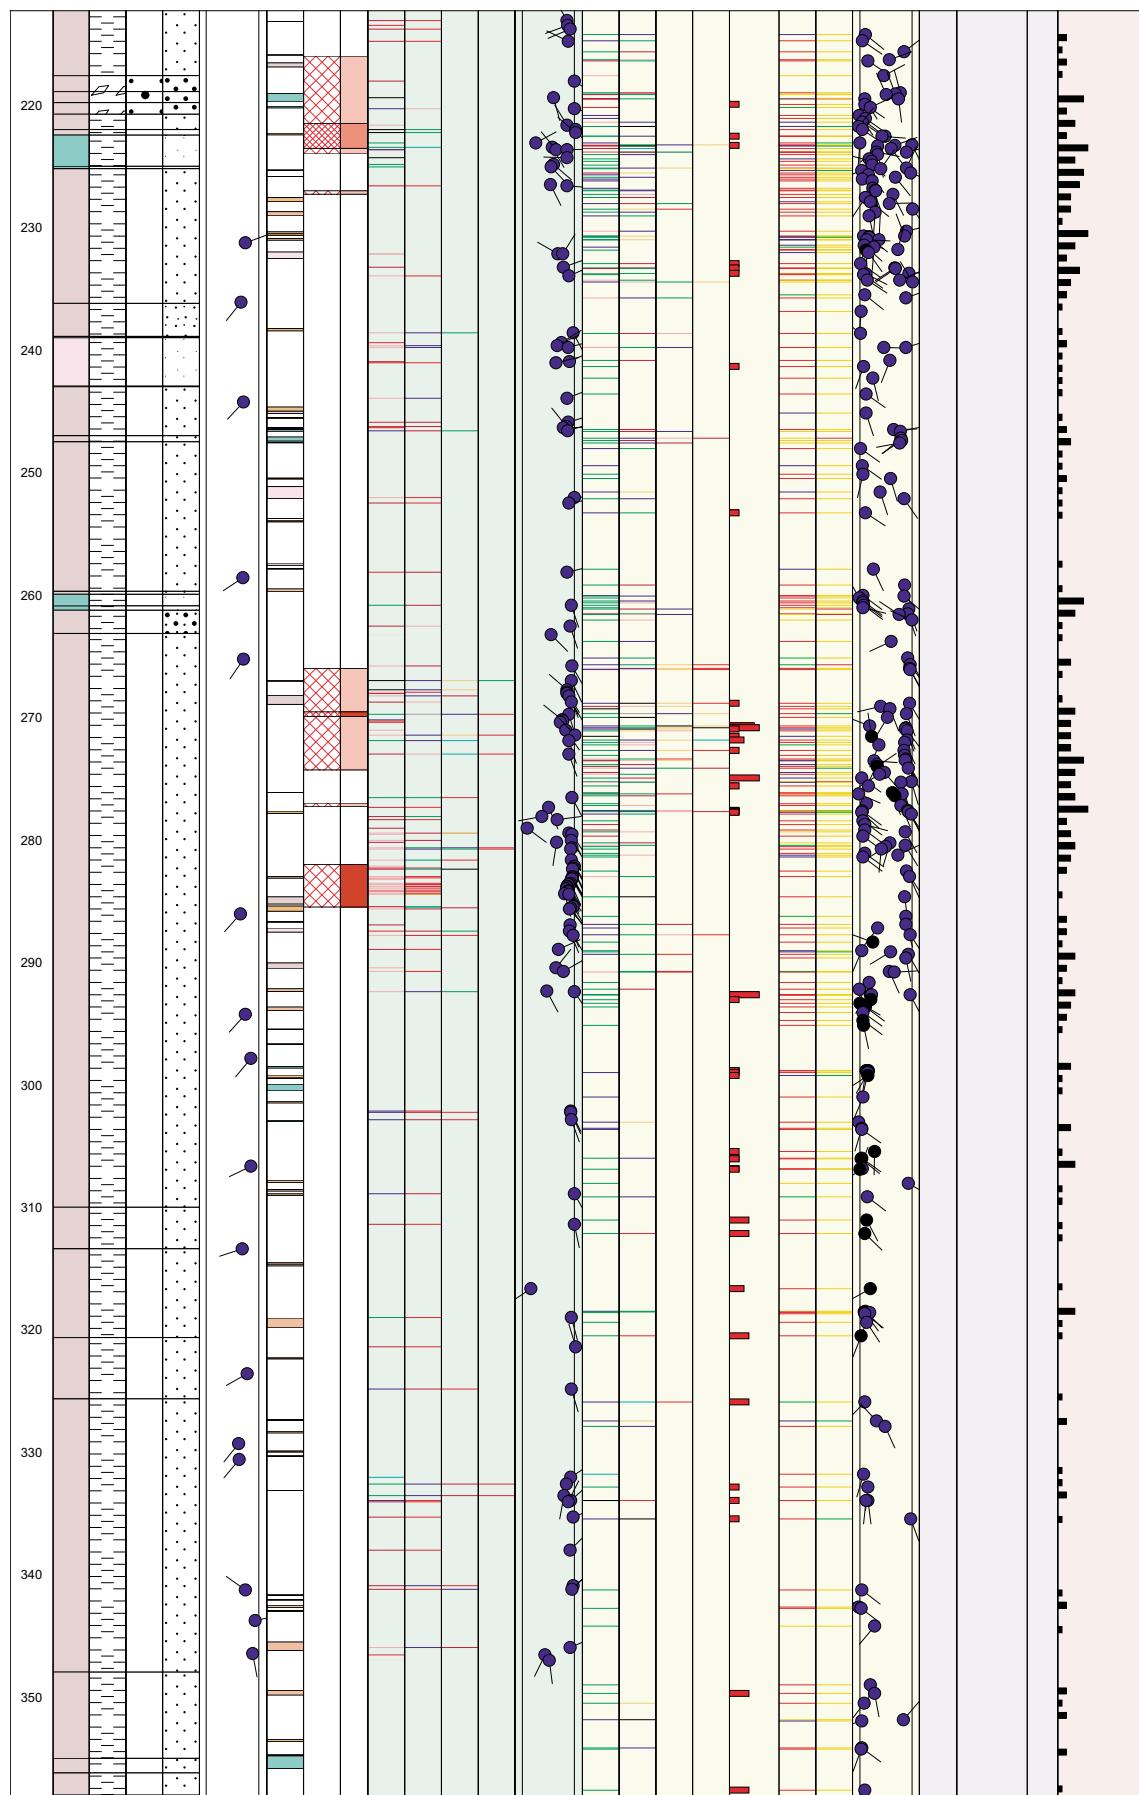

**FRACTURE DIRECTION**
